Donaldson's own thinking about the effect of debt upon financial risk leads him to the conviction that of the various common approaches to debt standards the most useful lies in coverage analysis—not, however, in terms of earnings, but in terms of cash flow. In order to provide a rigorous demonstration of this approach he develops a system of equations—mathematical but not elaborate—which take into account the principal determinants of cash flow. Postulating that management will be able from past experience to provide quantitative values for these determinants reflecting their probable behavior in recession, he thus offers a means of evaluating the risk that cash flow may descend to the region of *cash inadequacy* and, in the extreme, to the point of *cash insolvency*. Debt service is treated as only one of the several factors. "The recession cash flow analysis is therefore seen to be a necessary preliminary to a whole set of financial decisions involving fixed cash outflows, and the opportunity for long-term debt financing clearly cannot be decided independently of other purposes to which a willingness to bear increased risk might be put" (p. 215).

Application of his method to five of the companies—one from each industry—leads him to conclude that the conventional types of debt capacity standards are outmoded and that balance-sheet and income-statement ratios are inadequate as guides to decisions on debt policy. He concludes, further, that if financial officers would use the cash-flow approach they might see more clearly that debt policy is only one of the factors bearing on the financial risk and thus reach their decisions less arbitrarily and more rationally. The argument and the evidence are both persuasive.

Competition in the Aluminum Industry: 1945-1958. By MERTON J. PECK.
Cambridge: Harvard University Press, 1961. Pp. vi, 227. \$5.25.

Until recently, most beginning students in economics first learned about monopoly by being introduced to the Aluminum Corporation of America. As Professor Peck's study makes clear, the time has come for economists to find another "real-life" example of the sole producer to serve their pedagogical purpose. Indeed, the aluminum industry has now so far degenerated toward workable competition that it is no longer a very good example of oligopoly.

The steps by which Alcoa's complete control of aluminum reduction capacity in 1939 gave way to a one-third share in 1958 are succinctly described. Since the courts resolutely refused to order dissolution or divestiture, the decline of Alcoa is traceable to legislation and what may be a new form of antitrust—"regulation through public opinion, the vague consequences of Congressional displeasure, and the policies of miscellaneous executive agencies" (p. 1). That competition—given any reasonable definition of the term—has increased in the aluminum industry over the last twenty years is clear enough. The interesting question is how much (if anything) the economy paid in lowered efficiency to secure this increase in competition. Peck declines to consider this issue directly, possibly because the evidence does not permit an answer in which one can have much confidence.

Each new entrant to the industry since 1939 has owed its start to the bounty of government agencies during the Second World War or the Korean conflict. Yet the jibe often made that competition in aluminum is the result of artificial insemination is misleading. The major rivals created for Alcoa by government favor—Reynolds and Kaiser—were, of course, chosen instruments of federal policy. But then in a war mobilization, every firm that is conscripted or created is a chosen instrument. Did the government choose wisely? Though Peck does not say it, his results permit the inference that we would have had cheaper aluminum during the Second World War had the expansion of aluminum capacity been entrusted to the old experienced monopolist. Likewise, if the efficient production of aluminum ingot had been the only goal, the surplus government plants should have gone to Alcoa after 1945. In defence of federal policy, it can be said that the learning period for a new ingot producer is not long; and that by the early 1950's, Reynolds and Kaiser were able to take care of themselves in a free market. "In 1949, Alcoa not only was considerably larger than Reynolds and Kaiser, but it had approximately a 10 per cent cost advantage and considerably greater financial resources. But, just as the relative size of Alcoa is now nearer the other two, Alcoa's cost and financial advantages have also declined" (p. 18).

Peck apparently accepts the view that the government decision to break Alcoa's monopoly on ingot production was a good thing. (A plain statement of the author's personal preference seldom intrudes in this book.) He has, however, no enthusiasm for proposals that would use federal power to force a further increase in the number of firms. His reading of the evidence indi-

cates that barriers to entry are "very high" and, by implication, that these barriers are imposed by the heavy initial investment needed to begin efficient operation. He accepts (apparently) the argument, challenged by some authorities, that efficient ingot production requires vertically integrated firms. In any event, the addition of a few small firms is likely to have less effect on market behavior than the extent of the tariff on imports, the activities of the independents, and so forth. "Since entry, like everything else, has its price, public policy in these other areas, may deserve higher priority than extensive direct government intervention to encourage further entry" (p. 182).

Inevitably this study invites comparison with the subject's standard work by D. H. Wallace, *Market Control in the Aluminum Industry* (1937). The wealth of detail, manifest enthusiasm for the subject, and concern with policy alternatives that marked Wallace's book are not equaled here. In Peck's favor, it can be said that he tells us most of what we want to know about developments in the aluminum industry since 1945 with a minimum use of the jargon, quotation, and statistical minutiae that so often characterize "definitive" industry studies.

Add, also, that Peck offers a most promising contribution to the methodology of industry studies. In Chapter 11 an effort is made to relate the characteristics of aluminum firms to the type of research and development that they conduct. To this end, the inventions reported in trade journals from 1946 to 1957 are classified according to engineering category and place of origin (e.g. primary aluminum manufacturer, foreign sources). As the author notes, the conclusion that "even large firms focus their inventive activities in areas where the profits are relatively immediate and certain" is not surprising (p. 204). Nevertheless, it is reassuring to those of us who are constantly being reproved by publicists, sociologists, and our colleagues with cosmic interests, for maintaining a naive faith in the directive force of the profit motive.

DONALD DEWEY

Cartel and Monopoly in Modern Law. Reports to the International Conference on Restraints of Competition at Frankfurt am Main, June 1960.

Edited by the Institut für ausländisches und internationales Wirtschaftsrecht, Universität Frankfurt am Main and the Institute for International and Foreign Trade Law of the Georgetown University Law Center, Washington, D.C. 2 vols. Karlsruhe: C. F. Müller, 1961. Pp. xxx, 412; x, 604.

The adoption and administration of a fundamental economic policy, for both individual nations and international commercial affairs, rarely gets such a thorough discussion by such a distinguished body of experts as was given to the administration of antitrust legislation at the conference on restrictive trade practices and monopolies in modern law at the University of Frankfurt in June 1960. That policy, narrowly conceived, is one of preserving competition among business firms. Broadly conceived, and all the participants viewed it in its wider setting, the policy is one of obtaining all the economic, political, and social benefits of the greatest possible freedom for trade within a country and amongst the nations. Those who gave papers were divided

appropriately between members of the academic profession and leading administrators of agencies charged with enforcing antitrust policies in the various countries of Western Europe, the Common Market, and in the United States.

Whether out of deference to a common weakness of Anglo-American scholars in foreign languages, or because English is a universal language of economics, the papers in French and in German are translated into English. The papers given in English remain in that one language. In reading the translations, it is wise to check technical terminology with the original. Not all translators are economists.

While the title of these two volumes is *Cartel and Monopoly in Modern Law* (*Kartelle und Monopole im Modernen Recht*), the word cartel signifies restraints of trade, or collusion among firms—all sorts of collusion, whether in written agreements or simple understandings. Monopoly in the title signifies dominant power of a firm in a market. The subject matter is thus the legal doctrines about collusion of firms and about predominant power in a market.

European economic policy, as even the "man in the street" knows, has in recent years been dedicated to the proposition that the material wealth of each country and of its inhabitants can be increased by a greater degree of trade and specialization among the nations of that continent. That is the basic economic idea of the European Economic Community (the Common Market) established by the Treaty of Rome in 1957; and that idea was largely responsible for this conference.

The association between the policy of eliminating restrictions on international trade in the form of taxes and eliminating monopolistic practices is not generally brought to the forefront by the usual arrangement of academic courses; but the close association is often well stated and well developed in these proceedings, particularly by Eberhard Günther, head of the Cartel Authority of the Bundesrepublik, in his résumé of international trade negotiations from the early 1920's. While some attention is given to antitrust policy within individual countries, the major emphasis of this conference and of these papers is on international antitrust policy, particularly as this policy is formulated in the treaty establishing the European Economic Community and in the treaty establishing the European Coal and Steel Community. Because centralized, regimented economic systems border on many of the countries of Western Europe, and because the experience with legalized cartels is more immediate for many of the participants, the policy under discussion seemed much more crucial than it would in a country with an old legal tradition against monopolistic practices.

The first paper opening the conference, "Democracy and Economic Power," was by that long-time warrior against cartels, Franz Böhm who guided the 1957 legislation against restraints on competition through the legislature of the Federal Republic of Germany. Böhm's thesis is that of the pure liberal, namely, that concentrations of economic power are a danger to democracy and a violation of the principle of freedom and equity. For Böhm, economic freedom implies submission only to those costs which are necessary in production. Tyranny enters when costs can be imposed, or increased, by those having

any considerable degree of control over market prices and supplies. Böhm believes that market power leads to economic inefficiency, but his gravamen against collusion of firms and against monopoly power is the social and political danger that this power brings with it. All of this would have heartened a Brandeis, a Cardozo, or a Hand, for these men also realized that the exercise of legitimate legal rights might, on occasion, bring about situations on the markets which are deleterious to the general welfare. Böhm is suspicious of the legitimacy of all large agglomerations of economic power; and he fears their influence on the structure and actions of government. His ideas are clearly and forceably put, with perhaps a little more formalism than is usual in Anglo-American economic and political philosophy; but his insights are sharp and pertinent. The postulate that there is a close connection between political liberties and the structure of the economy—a postulate that Keynes accepted—is repeated by quite a number of those contributing papers, by Günther in his first paper, by von der Groeben, Hallstein, president of the Commission of the EEC, Ludwig Erhart, *et al.*

Since this conference was on modern national and international *law* regarding competitive behavior, the legal aspects of the economic policy receive very extensive and minute treatment. The legal side of this policy is often a very practical matter for lawyers and their clients; but there was no hesitation in speculating on what the law might be or ought to be. The legal aspects involve, in the first place, an examination of the precise meaning for different parties of certain concise constitutional formulations on collusion and on market power written into the treaties establishing the ECSC and the EEC. (In this brevity, the provisions resemble the Sherman Act.) The similarities and the differences in the basic provisions regarding competition of these two international economic units are extensively examined by a number of contributors—differences in the rôle of competition, in the control over mergers and consolidations, market power, etc.

The lawyers were also interested in the relationship between the laws in the various countries of the Common Market, termed “municipal law” in these reports, and the treaty provisions. If the treaty provisions are stricter than the law of a country, which prevails? And under what precise circumstances? When does a restraint of trade affect trade within the area of the Common Market? Which authorities, national or international, are competent to take action against restraints and predominant power? And what action or actions? How is uniformity of interpretation of the treaty provisions to be achieved? Who has power to investigate suspected contraventions, and how far does this power extend? What is the relation of private civil law, or the rules governing the relations between business firms, and the international law? Can a firm enforce a contract with another firm that violates policy established by international law? What exemptions from the policy of competition are present and what do these exemptions mean? What if the law of one member state is stricter than the international treaty provisions? To what extent can courts of one national exercise jurisdiction over firms domiciled in other nations but, in some way, affecting international trade and the first country’s domestic market? (The lawyer specializing in the conflict of laws

will have plenty of business!) Further, what about vertical price fixing? International patent licensing? What happens when the laws of one country expressly permit export cartels? To whom are appeals against administrative decisions on the legality of actions or conditions to be made?

These are some of the thorny legal points that will inevitably come up with the attempt to make Europe more of an integrated economic unit, while preserving the sovereignty of each country. As complicated as the problems are, there seems to be a strong will to solve them, together with patience to work out solutions.

Certain papers on the meaning of provisions against discrimination in the EEC and the ECSC treaties may be of more technical interest to economists. When is a difference in price evidence of monopoly power, and when is it an indication of the varying stresses of competition? Mestmaker, who is thoroughly familiar with U.S. law on this matter, gives an excellent analysis of the probably insoluble problem of the precise specification of unwanted discrimination. Raiser considers the issue of refusals to trade and monopolistic power in U.S. and German laws.

These were significant contributions by U.S. experts; but papers by Americans are being neglected in this review, since their contents will be more familiar to the American reader. There is an excellent survey of U.S. law by Irston Barnes, a paper on concentration by Tait; and papers by Rashid, Schwartz, Kronstein, and Kingman Brewster, Jr., while Corwin Edwards gives a penetrating report on a working-group discussion.

As is usual when measures for carrying out a policy are being discussed, some recalcitrants take a few pot shots at the policy itself by their suggestions for putting the policy into effect. In this conference, there were murmurs, most audible among the French participants, favoring the propositions that stability of price through collusion is also an economic benefit, that large size has its advantages, that the firm with dominant power may be able to afford more for research and technical advance, and that the giant firm is evolving into a public service institution.

The predominant tenor of the conference, however, was completely skeptical of the benefits of business collusion; and the whole purpose was to formulate those precise circumstances under which it could be reasonably presumed that collusion is generally an evil and therefore to be banned per se. The choice is between establishing general rules stipulating conduct which is forbidden and that which is allowed, on the one hand, or relying on administrative action when evil results or restrictions on trade arise. Those who wanted to permit collusion and monopoly power and rely on administrative agencies to check abuses of such power were here in a minority. Lawyers who are not perverted by a belief in the evils of competition probably have a predilection for rules rather than for administrative action, particularly when evidence is so difficult to obtain and conclusive results so difficult to establish. When it comes to oligopoly and market power, the law is still unable to write bounds for an elusive phenomenon; so, for want of ability to set down general rules, authority is given to intervene in case of abuse of market power.

After perusing these two volumes of proceedings containing many learned and highly technical papers, each worth a review by itself, the economist must come away with mixed emotions. He must be struck by the extent to which the establishment and the execution of a fundamental economic policy rests, not with economists, but with the legal profession. Even on technical matters like the rules of competition, the economist is displaced by the lawyer. Do economists as a profession suffer from fatigue at the dull task of formulating in written statements precise prescriptions for an economic policy, or are they fatigued by the task of interpreting the meaning of a rule for specific situations? Whatever justification the economist may give, an acute French lawyer chided economists for not giving more aid in the difficult problems that the lawyer is facing; and Barnes made a depreciating reference to the economist's preference for playing with models rather than tackling the problems of specifying the proper area of competitive behavior.

Another matter which will strike the economist is the extent to which the economic structure is an organic unit as Marshall conceived it. One cannot touch one part without a reaction in other parts. International antitrust policy is connected with many other features of national economic policy. It will be affected by the tax policies of individual states, by monetary and fiscal policy, subsidies, dumping, government enterprises, foreign exchange rates and foreign exchange controls, etc. Each one of these may affect the competitive position of firms in relation to each other. This interrelationship was alluded to in several papers, but perhaps an economist was needed to give emphasis to the interdependence of all economic measures.

Finally, every economist with any sense of economic history must be impressed, after reading these volumes, with the *Müh und Weh* which is involved in attempting to establish, or rather re-establish, by treaties and by international economic agencies that economic unit which was Europe before the First World War. The destruction of that unit is what Keynes so vehemently protested against in his *Economic Consequences of the Peace*. Now, after a Second World War, statesmen with far more vision acquired by experience are attempting to rebuild that unit to obtain the benefits of trade which Adam Smith pointed out so long ago in his *Wealth of Nations*.

Regulation and Competition in Air Transportation. By SAMUEL B. RICHMOND.
New York: Columbia University Press, 1961. Pp. vii, 309. \$7.50.

For those familiar with the recent literature on the economics of air transportation, one can convey a good deal about Professor Richmond's book by saying that it follows more in the Cherington tradition than in that of Wheatcroft: it is long on description and short on analysis. Perhaps Richmond's greatest contribution flows from the easy-going—even entertaining—manner in which he treats the history of U.S. commercial air transportation. For this reason alone, the book will have considerable appeal in some quarters.

The over-all objective of Richmond's book is to explore the interaction and interrelationships between regulation and competition. In a highly regulated industry competition is nevertheless recognized as desirable, even essential; the problems arise when one attempts to specify how much and what kind of competition. Richmond traces the changing views of the regulating agency over time and as the economic character of the industry changes. He spells out quite traditionally the basic concept of competition and discloses the forms of competition possible and prevalent in air transportation.

With considerable detail, the author also covers the methods which the Board can employ to "create" and control competition. He then illustrates and discusses the Board's capriciousness with respect to the use of competition as an efficient instrument for bringing about a rational commercial air transport system.

At the end of his book, Richmond focuses upon a specific period—1955 to 1957—and digs into masses of statistics, Board decisions and other material to determine the Board's "criteria for competition" and its bases for selecting specific carriers to introduce service between given pairs of cities. Finally, the author surveys the competition resulting from the 1955-1956 brace of route awards to determine if and to what extent the Board's pre-decision objectives were achieved.

Richmond usually asks the pertinent questions, but too often either furnishes no answers or employs the technique of assertion-without-proof. For example, while discussing "the rationale for regulation," Richmond raises the crucial question whether air transportation is naturally monopolistic and asserts that it is without a shred of proof. Then, throughout most of the book, he takes as given that which has been proven only by assertion.

The extent to which assertion is substituted for analysis is again indicated by the following sentence appearing in the course of a discussion of the general nature of competition: "As long as the number of firms in the industry is sufficiently large to assure the effectiveness of competition in individual (city-pair) markets, the actual total number of firms in the industry is not a matter of great economic importance." The author certainly ought to recognize that the actual number of independent firms in a monopolistically competitive industry can indeed have tremendous economic importance. For example, fewer trunk airlines would find it easier to agree on such things as the appropriate rate level and rate structure and might readily and collusively reach decisions as to what are and what are not "acceptable" avenues of competition. Also, a reduced number of buyers for transport aircraft could easily have a profound effect upon the types of aircraft manufactured and upon the industry's general propensity to innovate.

One of the most serious criticisms of Richmond's study is that it deals almost entirely with supply-side considerations and only rarely with demand. For instance, when discussing the notion of "excessive competition," the author is concerned only with the impact of route competition on airline costs, ignoring entirely the relationship between the level and character of competition and the demand in a city-pair market. This is particularly regrettable because the statistical techniques Richmond employs make it possible to draw

some interesting conclusions about the effects of new route competition upon demand.

Again, when considering the problems attendant to the subsidization of weak routes with the revenues from stronger ones, Richmond often fails to recognize that internal subsidy may be a means of maximizing long run profits. Instead, he usually focuses on such behavior only in a short-run context. Also lacking is discussion of the explicit position of the Civil Aeronautics Board with respect to internal subsidy. This shortcoming appears most dramatically when the author notes the practical necessity of internal subsidy but completely ignores the fact that the Board's creation of competition on the rich routes could have the perverse effect of increasing carrier costs on such routes to the point where internal subsidy in the long run becomes impossible.

In general, Richmond is not critical of the Civil Aeronautics Board and its policies toward competition. It is not entirely clear why this should be the case, particularly since the author often accurately describes Board policies which, for an economist, must surely be anathema. For example, in citing the level of intercity traffic as one of the several criteria employed by the Board in determining the proper measure of competition in a city-pair market, Richmond is cognizant that the thresholds of traffic which the Board employs change very little with time in spite of the fact that the basic economics of the industry—the production function of air transport—has itself changed drastically through time, making changes in Board policy mandatory if the results contemplated by the Federal Aviation Act are to be obtained.

Richmond does provide some clever and useful insights into the problems of regulating a new mode of transportation. One of his most attractive concepts is that of "The Life Cycle of City Pairs." Without question, consideration of the Civil Aeronautics Board's attitude toward competition is more meaningful when viewed in the light of the stage of development in which a city-pair market is found. Those interested in transport economics will find this "life cycle" approach useful in numerous ways.

Richmond states explicitly that the purpose of this book is "to define the criteria and standards which the Board used in its decisions to increase the amount of authorized competition." He discusses in detail route awards from late 1955 onward and uses masses of data which were punched on IBM cards and analyzed, grouped and re-grouped through sorting processes in order to display the *ex post* effects of the Board's creation of competition. He compares the *ex post* data with the intent of the Board as Richmond adduced it from the formal decision which "created" the competition. Of necessity, the determination of the intent of the Board is largely subjective and opens to question the efficacy (and value) of comparing "hard" (and *ex post*) data with a "soft" (and hypothetical) assumption. But for all the traffic data compiled by the author or otherwise available to him, at no point are pre-1955 and post-1955 concentration measures systematically given. Therefore no specific evidence is presented as to whether the Board succeeded in reducing concentration in the trunkline portion of the air transportation industry.

Towards the end of his book, Richmond offers a caveat that not too much

reliance can be placed on the type of statistical evidence upon which the analysis of the book is very much based. The author clearly recognizes the situation: the statistics are often misleading. With this, one cannot argue,

AARON J. GELLMAN

Glencoe, Illinois

Die Konzentration in der Wirtschaft. Edited by HELMUT ARNDT. Schriften des Vereins für Socialpolitik, 3 volumes. Berlin: Duncker & Humblot, 1960. Pp. xv, 781; vi, 678; iv, 463. DM 78.60; 69.80; 58.60.

This important work contains a collection of approximately sixty articles submitted in September 1960 to the conference of the Verein für Socialpolitik which dates back to 1872.

The work is divided into three parts. Volume 1 (781 pages)—the present state, causes and effects of concentration—is mainly descriptive and gives a very general idea of the various aspects of the problem, from the concentration of industry to that of income and wealth. Although a major part of this first volume is devoted to the study of the German economy, it also includes articles on other countries, notably by P. E. Hart for the United Kingdom and Carl Kaysen for the United States, but without any effort towards international comparisons. There is valuable information in the different articles, but the statistical data would have been of more value had it been less dispersed. The part played by government and other public bodies in economic activities is also considered here, somewhat unexpectedly.

Volume II (678 pages) deals with the causes of concentration in its technical, legal, social, political and taxation aspects. It is rather difficult to determine whether it is question of the influence of these different factors on concentration or vice versa. The study on the United States by J. M. Blair constitutes however, an exception to this observation. Many of the articles in this section would be more appropriate in Volume III.

The final volume is in fact short (320 pages), but deals with the effects of concentration on a great diversity of items, such as costs, shareholders' rights, industrial location, democracy, economic development, advertising, public knowledge of the business world, etc.

Generally speaking, more attention could have been paid to the classification to the different subjects in the three parts, and even to the criteria chosen for these main divisions. But this is a minor defect. With regard to the basic problem, there are two all-important considerations: how far exactly does the scope of the subject extend, and what contribution does this work make to the statistical analysis of concentration?

As far as the first point is concerned, there may be some confusion in the U.S. reader's mind, accustomed as he is to a more limited conception of concentration: industrial concentration. Even restricted to this field, there is further risk of misunderstanding; the connection between competition and industrial concentration has not been clearly defined. Several legal articles, including a very good one on mergers (E. J. Mestmäcker), compare various features of different national laws regarding corporations. One paper on trade agreements (H. König) describes the evolution of cartels in the German econ-

omy as a whole and in certain sectors or markets. But, unfortunately there is no general economic study on mergers in Germany, such as those by J. F. Weston or R. L. Nelson for the United States.

With regard to the second point, the measurement of concentration, the reader will be well satisfied. The article by H. Kellerer, of Munich, is a comprehensive and painstaking survey of the major contributions to the statistical literature. It may perhaps be regretted that only a passing mention is made of the controversy (S. J. Prais-M. A. Adelman) between the two kinds of methods of measurement, concentration *vs.* inequality. G. Fürst, Head of the Federal Statistical Office in Wiesbaden, clearly adheres to the first type in an article which contains the most complete statistics on the concentration of firms and plants in Germany.

There is no doubt as to the value of Arndt's work. For the layman interested in concentration—and the recent inquiry ordered by the Bundestag has popularized the subject—this book will constitute a useful source of information. The same is true for those outside Germany who have no access to official statistical data. Moreover, this book represents an important contribution to the knowledge of present German industrial structure.

Land Economics; Agricultural Economics; Economic Geography; Housing

Natural Resources and Economic Growth. Edited by JOSEPH J. SPENGLER.
Washington: Resources for the Future, Inc., 1961. Pp. xii, 303. \$3.50.

This volume is the proceedings of a conference held at Ann Arbor, Michigan, in April 1960 under the sponsorship of Resources for the Future, Incorporated, and the Committee on Economic Growth of the Social Science Research Council. The authors and discussants of the various papers were struggling with a series of complex and weighty questions: What has been the role of natural resources in determining the rate of economic growth of nations and regions? What is it likely to be in the future? Is specialization in the export of primary products likely to be conducive to the development of an underdeveloped country? What should be the objectives of public policy toward natural resources and to what degree have they been accomplished? With a few exceptions, these questions suffered only superficial bruises from the attack by the conference participants.

A major recurring theme of the conference was that technological change has progressively reduced the importance of a nation's resource endowment as a determinant of its rate of economic growth, and that the process of economic growth itself tends to result in a further reduction. A second theme, partially conflicting and partially complementary to the first, was that the particular historical composition and geographical distribution of economic growth has been, and continues to be, significantly influenced by resource availabilities. The first position is defended most strongly by T. W. Schultz, who points to the effectiveness of technology in forestalling the appearance of

a shortage of agricultural land in the United States, and by J. H. Adler, who emphasizes the "passive" role of resources as the "object of development." In developing the second theme, H. S. Perloff and L. Wingo make a strong case for the historical importance of the resource endowment as a determinant of the course of economic growth in the United States. Spengler, in his excellent "Summary, Synthesis and Interpretation" of the conference, also emphasizes the historical role of resources in shaping growth. Additional comments along this line were made by some of the discussants, most notably and incisively by W. N. Parker.

Chandler Morse and H. J. Barnett contribute a theoretical analysis of the validity of the Malthusian and Ricardian views of resource scarcity under conditions of no exogenous technological change. Although their model has some shortcomings—in particular, it assumes zero foresight and thereby waives completely the problem of intertemporal allocation—it serves as a useful framework for clarifying the concept of resource scarcity and cataloging the qualifications to the Malthusian and Ricardian views. McGann's paper is a freewheeling tour into the distant future. His exercise in fearless growthmanship suggests that present and presently foreseeable technology probably can turn the world into a densely populated (materialistic) Utopia in the course of several centuries, but achievement of this goal will require appropriate policies, which may not be forthcoming. J. S. Bain provides a useful review and critique of natural resource policies in the United States.

The success of the Perloff-Wingo, Morse-Barnett and McGann papers stems in part from the fact that their approach is theoretical and/or quantitative; and this approach provides a degree of clarity in the framing of questions that is lacking in most of the rest of the volume. Unfortunately, theoretical precision is often absent even at points where it could readily be achieved. The discussion of the "importance" of resources in economic growth suffers from repeated failure to make an elementary distinction between the functional relation $g(R)$ connecting the resource endowment and the growth rate, and the "marginal product" of resources in terms of growth when the resource endowment is R_0 , $g'(R_0)$.

Even if clarification of this relatively simple matter had been achieved, the discussion of many important issues would necessarily have remained qualitative and impressionistic for want of a fully adequate theoretical framework. Such a framework should clarify the relationships between economic growth and such influences as (a) the rates of technological changes in resource industries and elsewhere, (b) the uncertainty about the course of such change in the future and about the existence of additional supplies, (c) the extent of foresight in the anticipation of resource scarcities and the mechanisms by which such anticipated scarcities are reflected in markets and in public policies, and (d) the extent to which economic growth may be freed from resource constraints by substitution possibilities in production and by income and price elasticities of demand. Finally, of course, it would be desirable to have all of this analysis incorporate locational factors. This is obviously a tall order. It seems to this reviewer that it will have to be met

if understanding of the relationship between natural resources and economic growth is to progress much beyond the unsatisfactory level revealed at the Ann Arbor conference.

Council of Economic Advisers

Labor Economics

The Structure of Collective Bargaining. Edited by ARNOLD R. WEBER. New York: The Free Press of Glencoe, for the Graduate School of Business, University of Chicago, 1961. Pp. xxxii, 380. \$8.50.

The pure theory of value leaves little room for decision-makers; the logic of markets determines all. Yet when economists assess the significance to public policy of the roles played by the parties to collective bargaining, informed opinion runs a wide gamut. Bargaining is sometimes seen as a mirror of events it cannot touch; or as a transmission line for forces it can but slightly alter; or as a catalyst in whose presence change may quicken or slow; or as a prime mover of the economic order.

Probably bargaining has not generally or consistently influenced all of the variables prominent in economic analysis: wage-price levels, functional shares, geographic and occupational differentials. Evidence from empirical studies is certainly ambiguous. But that bargaining has affected these variables in the short run and that it continuously impinges upon the economy in other crucial ways is a major and reasonable premise of such studies as *The Structure of Collective Bargaining*.

As defined in the Introduction, structure means size of the negotiating units in terms of the number of employees and firms; industrial, occupational, and geographic scope of the units; locus of authority within units—and without units in instances of governmental authority; and relationships among units. With much skill and occasional daring, the contributors to this volume have put together an authoritative source of information on the complexities of bargaining structure.

Part I deals generally with the determinants of bargaining structures (Neil W. Chamberlain) and with recent trends in the growth and scope of units (E. Robert Livernash). In one of several excellently edited discussions, Dunlop develops important distinctions that are to inform much of the later writing: the election district defined by statute (and called "bargaining unit" in the law); the negotiation area or constituency for whom bargaining is carried on; and the broader area of impact of negotiations. Legal and economic misconceptions have resulted from failure to make these distinctions.

Part II takes up management's bargaining objectives as related to structure (Edward L. Cushman and Herbert R. Northrup in separate pieces). Here we find forceful expressions of management's view that bargaining (negotiating) units ought to be limited to individual companies or to "profit centers" within companies. How this might be accomplished is not spelled out.

The discussion that follows shows how questions about centralization of bargaining are related to questions about democracy within unions. Several memorable passages will be often quoted in future writing on this subject. Herbert R. Northrup, until recently a consultant to General Electric, holds forth on the Company's dedication to union democracy:

However, under General Electric's policy we prefer to have a democratic union. Then if we have a situation where we'd like to see the membership overturn the position of the union leaders, we can put constant pressure on the union to subject the various issues to a membership vote. We can also encourage the people to go to the union meetings and vote.

A little later on, J. Wade Miller of Dewey and Almy Chemicals points out that many corporate officials would prefer to deal with highly centralized unions who can assure ratification of terms by the membership. Northrup rejoins: "I would agree with you—except for GE. Democracy has paid off for us."

The remainder of Part II is an analysis of data that bear upon the actual size and scope of bargaining units in the United States (Peter Henle) and unions' perspectives on centralization (George W. Brooks). Two interesting and somewhat conflicting views here are Henle's doubts about the extent of a trend toward centralization of bargaining and Brooks' contention that such a trend does exist, that management often promotes it, and that unions must resist it if they would preserve the grass-roots vitality of the labor movement.

Part III examines problems of bargaining in five industries and one company: meat packing (Ralph Helstein), steel (William G. Caples), chemicals (J. Wade Miller), airlines (Charles M. Mason), construction (John T. Dunlop), and International Harvester (Robert B. McKersie). The differences among these industries are so substantial that the reader is presented with fascinating opportunities for cross-comparisons with respect to technology, governmental constraints, labor organization, and market structure.

The paper by Caples (of Inland Steel) and the discussion that follows between him and George W. Taylor, who was chairman of the 1959 Steel Fact-Finding Board, provides valuable material, and as might be expected, defines the issues sharply. One of the pressures bearing upon the 1959 negotiations—or upon the reluctant negotiators—is brought out in Taylor's reference to the government's attempt to use "the steel industry as a vehicle for the development of a national wage policy," a policy based upon the criterion of productivity. The impact of steel negotiations upon wages throughout the basic industries has obvious importance to the structure of bargaining in these other industries. Unfortunately, this impact is not dealt with at any great length.

Dunlop's treatment of construction continues his penetrating analysis of this industry and his attempt to work out implications for a general theory of industrial relations. There is an excellent description of the way forces from labor and product markets condition the bargaining structure with respect to regions, crafts, and branches of the industry. Illustrating these

forces, the author cites the function of prohibitions against piecework and of uniform jurisdictional rules, both serving to standardize labor costs over an area and placing the burden of competition among enterprises upon such other factors as managerial efficiency.

In Part IV of the book, Douglass V. Brown and George P. Shultz discuss public policy and the structure of bargaining. The authors show how the absence from policy of any clear intention to affect structure has led to confusion in statutes, court interpretations, and NLRB decisions. But beyond an endorsement of industry-wide bargaining and of the notion that somehow employers should have a voice in the designation of the appropriate bargaining unit, there are few guidelines laid down for a clearer policy.

The conclusion of the book is George W. Taylor's essay on bargaining in transition, a fine work of criticism and proposal. Collective bargaining is a liberty to select and define problems, writes Taylor; it is not a rigidly constituted institution. Therefore, it was a mistake to set down "refusal to bargain" as an unfair labor practice since this requires a definition of bargaining and a curtailment of liberty. In a similar vein he criticized the Bill of Rights of the Landrum-Griffin Act. A discussion of national emergency strikes and, more generally, of the obsolescence of the strike weapon round out a stimulating presentation.

A final, satisfying impression gained from this valuable book is this: the study of industrial relations as practiced by experts has progressed well beyond the stage when the distinction between institutional and theoretical approaches—and reproaches—was held to be especially fruitful. Major issues do not permit analysis without attention to both economic theory and the institutional context of its operation.

Michigan State University, Oakland

Wagakuni chingin-kōzō no shiteki kōsatsu (A Historical Study of Japanese Wage Structure). Prepared by Shōwa Dōjin Kai. Tokyo: Shiseido, 1960. Pp. xv, 550. ¥2,000.

The authors of this volume are ten members of the committee on wage structure of *Shōwa dōjin kai*, a research organization composed of interested university professors and research economists associated with government and business.

The primary objective of the book is to elucidate the socio-economic forces which have shaped the present Japanese wage and employment structure. Part I summarizes quantitative indicators of wages, employment, and wage differentials as time series or, in some cases, as values for selected years from the past fifty years. Part II describes the evolution of labor markets and wage payments over the entire period of modern Japan (officially dating from the Meiji Restoration of 1868). Part III discusses the major sources of data and presents detailed tables of wages and employment by industry, occupation, firm, and geographical division, together with other useful historical statistics. The appendix reproduces the long-neglected but extremely im-

portant investigations by the Japanese government of wage-payment practices current in 1922.

Part II is the core of the volume. It is a detailed historical study of the changing characteristics of Japanese labor markets and wage-determination practices. The study has far-reaching significance, for it destroys, once and for all, many of the unsound interpretations of Japanese wages, employment, and industrial relations since the Second World War.

In addition to collecting, reproducing, and annotating the important wage and employment data and historical documents, the authors have examined the relationship between changes in average real manufacturing earnings on the one hand, and changes in aggregate economic activity, employment, and labor productivity on the other (Part I, Ch. 1). The results are disappointing; no significant relationship has been found between earnings and any one of these variables. However, the authors do not appear to appreciate the serious implications of these negative results. If they were to be taken seriously, they would compel us to explain the behavior of Japanese wages independently of the variables ordinarily deemed relevant. The fault lies with their handling of the correlation analysis.

It is found that Japanese wage differentials, like their counterparts in other countries, tend to narrow or widen as economic conditions improve or deteriorate (Part I, Ch. 2). In explaining these variations, however, the authors advance an untenable hypothesis of leads and lags among occupations, industries, and geographical areas. It is alleged that wage increases first take place in the key occupations belong to expanding industries in major urban centers and spread to other occupations, industries, and regions, and that wage differentials widen during the first stage and narrow as the laggards catch up to the leaders (p. 154). This hypothesis would make wage differentials widen during prosperity and narrow during depression, contrary to evidence.

Quite often, the authors go beyond the permissible range of inference from the data presented. At one point, it is argued that wages for various occupations were competitively determined in the market prior to the 1930's but that the ability to pay of a firm or industry has since been a predominant factor in wage-determination (pp. 101-2). Strangely enough, this is said to follow from the observation that the rank correlation coefficient for various occupations between a given earlier year and a later year decreases as the interval of the correlated pair of years increases. Further, it is alleged that wages at or near the bottom of the wage structure are regulated by agricultural wages and rural living standards (pp. 103, 153). The role of agriculture as a *deus ex machina* that determines the floor of the wage structure is not consistent with the analytical framework of general interdependences espoused by the authors. Curiously, there is no systematic examination of variations in intersectoral wage differentials.

Despite these analytical shortcomings, this volume contains sufficient data to engage interested economists in further rigorous analyses of the Japanese wage and employment structure for many years to come.

The London School of Economics and Its Problems, 1919-1937. By LORD BEVERIDGE. London: George Allen & Unwin, 1960. Pp. 138.

The scope of this interesting volume is the period when Sir William Beveridge was director of the London School of Economics and Political Science (L.S.E.). During this time a suitable building was found for the school in the Bloomsbury area of London; economics as a field of study was defined in scope and method; political activity was successfully pursued by distinguished faculty members; and academic self-government was won. These years were described by Sidney and Beatrice Webb, who had established the School in 1895, as its "re-foundation."

It is well to remember that the School, as described by Sidney Webb, was originally "two small hired rooms in John Street, Adelphi, destitute even of a promise of endowment, without professors or students, and devoid of any visible chance of academic status." Today it is an institution of international reputation known not only for its range of curriculum offerings in the social sciences, for its research and library facilities, and for its distinguished (and controversial) faculty. The student body is drawn from all parts of the world, more recently from the less developed countries.

A number of articles have been written about the School, but I have not found any that captures the academic vitality and challenge which the School and its program conveys to British and overseas students alike. Lord Beveridge's volume is more successful, but it is hoped that someone, some day, may write a full-blown, well-documented history of what is affectionately known throughout the world as the "L.S.E."

Many famous lecturers have graced the School's classrooms including Clement Atlee, Arthur L. Bowley, Edwin Cannan, Hugh Dalton, Goldsworthy Lowes Dickinson, Lawrence Dicksee, Herman Finer, Herbert Foxwell, Theodore Gregory, Edward Jenks, Lilian Knowles, Harold Laski, Bronislaw Malinowski, Arnold Plant, Lionel Robbins, Arthur Salter, Richard Tawney and Graham Wallas. They represent a veritable WHO'S WHO in the British social sciences.

The achievements of Beveridge were apparent in the establishment of the Commerce Degree; in the emphasis on research as well as on teaching as a professor's charge; and in the establishment of a link with the United States. Beveridge did not succeed, however, in implementing the Webbs' belief that economics was not "an analysis of concepts but an inference from facts of society after unsparing examination."

While director of the School and thereafter, Beveridge held the opinion that it is "irrational to study society without studying the human material from which society is made." His experiments in this direction were generally unsuccessful. "Even after forty-two years," Beveridge writes, "the London School of Economics and Political Science had not achieved the purposes for which Sidney and Beatrice Webb had brought it to birth—the purposes of breaking up economics and making it a science in the true sense of that word, and the purpose of making the circle of the Social Sciences complete." But

he adds that the School had, with the neverfailing support of the Webbs, "become a rather wonderful place."

The last chapter of Beveridge's book arises from a lecture given at the School to celebrate the Centenary of the Webbs. Here he tells something of his forty years' friendship with the founders, a friendship which was not marred by differences of political opinion or social outlook.

Those who wish to study the School's developments further may do so in Beveridge's book, *Power and Influence* (New York, 1955); Margaret Cole's *Beatrice Webb's Diaries, 1912-1924* (New York, 1953); and Frederick Hayek's "The London School of Economics 1895-1945," *Economica*, February 1946.

HALL, M., KNAPP, J. AND WINSTEN, C. *Distribution in Great Britain and North America—a study in structure and productivity*. New York: Oxford Univ. Press, 1961. Pp. xiii, 231. \$10.10.

Part I "provides a statistical summary of the structure and productivity of distribution in the United States, Great Britain and Canada, and also of the variations in the numbers and size of distributive outlets, and in productivity." Part II is concerned with the conceptual problems—in particular, the concepts of distributive output, efficiency and economies of scale. Part III "contains the main part of the statistical analysis. It is, basically, an attempt to explain how the size of the market and other environmental factors affect the scale of retail enterprise and the salesproductivity of labour. . . ." SPRAOS, J. The decline of the cinema: an economist's report. London: Allen & Unwin, 1962. Pp. 168.

The author's object is "to discover, so far as possible, the relationships underlying the facts, the patterns behind the events, the economic logic underneath the behaviour of an industry in decline, and, in the light of these findings, to discuss the economic future of the cinema and appraise the policy issues raised."

Among the underlying facts examined statistically are the influence of television, cinema closures, and the contraction of film output. The behavior of prices and costs is also examined. Alternative policies are considered.

Land Economics; Agricultural Economics; Economic Geography; Housing

BIRD, A. R. Surplus—the riddle of American agriculture. New York: Springer, 1962. Pp. 128. \$3.75.

Written primarily for the non-economist. The author addresses himself to the question: "How can we reduce the food surplus, increase farmers' incomes and still cut farm program costs?" His criticisms of the present program are cogent. His own program involves the use of marketing quotas, land retirement, measures to encourage farm families to retrain or retire, and continued research.

NOTES

A nominating committee consisting of Theodore W. Schultz, chairman, Dorothy C. Bacon, Richard E. Caves, Rendigs Fels, Douglass C. North and Robert Solow have submitted the following slate of nominees for 1963 officers of the American Economic Association.

President:

Gottfried Haberler

President-Elect:

George J. Stigler

Vice President:

Gardner Ackley

Abba P. Lerner

Jacob Marschak

Tibor Scitovsky

Executive Committee:

William J. Baumol

Evsey D. Domar

Richard B. Goode

William C. Hood

Representative, Social Science Research Council:

Franco Modigliani

Representative, American Council of Learned Societies:

Simon S. Kuznets

The annual meeting of the Association will be held in Pittsburgh, Pennsylvania, December 27-29, 1962, with headquarters at the Penn-Sheraton Hotel.

Increase in Rates

At the March 23-24, 1962, meeting of the Executive Committee of the American Economic Association, it was decided to adopt the following rate schedule, effective as of January 1, 1963:

Annual dues	\$ 8.00
Family membership	1.00
Junior (student) membership	4.00
Subscribing membership	10.00
Contributing membership	25.00 or more
Subscription to the <i>American Economic Review</i>	8.00

The members of the Executive Committee felt this action was necessary to enable the Association to continue present services to its members and to meet rising publishing costs of the *American Economic Review* and a new edition of the *Handbook*. It should be noted that membership dues and subscription rates have not been changed since 1950. The present schedule of rates is well below that of most other professional organizations.

HAROLD F. WILLIAMSON
Secretary

The One-in-a-Thousand Population Census Sample

The Bureau of the Census is planning to make available on a cost basis reels of magnetic tape or a set of punchcards containing the separate records of the population characteristics of each of approximately 180,000 persons, comprising a one-tenth-of-one-percent sample of the population of the United States. The information contained on the record will comprise substantially all of the characteristics of the persons as enumerated in the 25-percent sample portion of the decennial population census of 1960. Records also will be made available as a set of 180,000, 80-column punchcards. It is anticipated that these materials will be available during the latter part of 1962. The cost to each subscriber will depend upon the number of subscriptions. It is expected that the cost will be between \$4,000-\$7,000 each. Further information concerning this sample may be obtained by addressing an inquiry to the Director, Bureau of the Census, Washington 25, D.C.

New Publication

Announcement has been made of the forthcoming publication of a journal for foreign agriculture, *Zeitschrift für ausländische Landwirtschaft* under the editorship of Otto Schiller and Hans Wilbrandt in collaboration with the German Agricultural Society (DLG) in Frankfurt/Main. There will be a concentration on the role of agriculture in developing countries covering a wide range of agricultural and land problems in their socio-economic context. The journal will be published three times a year. It will be in German with summaries in English, French and Spanish. Communications about the journal should be addressed to the editorial office, Berlin-Dahlem, Podbielskiallee 64.

Deaths

- Bonnar Brown, Stanford Research Institute, May 11, 1961.
 Robert L. Carey, Columbia University, December 31, 1961.
 William J. Coyne, Chevy Chase, Maryland, October 8, 1961.
 Leonard Drake, Philadelphia, Pennsylvania.
 Floyd B. Haworth, emeritus professor, January 27, 1962 in Fresno, California.
 George B. Hill, Van Nuys, California, February 19, 1961.
 David Ivor, University of Western Ontario, London, Ontario.
 Julius Klein, Washington, D.C., June 1961.
 Harlan L. McCracken, Baton Rouge, Louisiana, July 1, 1961.
 Leo K. Mayer, Manhasset, L. I., New York.
 Paul J. Meier, University of Massachusetts, February 7, 1962.
 John E. Orchard, emeritus professor, Columbia University Graduate School of Business, January 28, 1962.
 Howard W. Saisslin, Denver, Colorado.
 Stefan Stykolt, University of Toronto, February 13, 1962.
 Michael T. Wermel, dean of the College of Business Administration, University of Hawaii, February 6, 1962.
 Virgile Wilhite, University of Oklahoma, January 27, 1962.

Retirements

- John Ewing, former chief, International Activities Division, U.S. Bureau of Employers Security, now consultant to the Bureau.
 E. E. Hale, University of Texas.
 Elmo P. Hohman, Northwestern University.
 Ichiro Nakayama, as emeritus professor, Hitotsubashi University.
 Richard M. Snyder, University of Miami School of Business Administration.

Paul S. Taylor, University of California, Berkeley.

Carroll S. White, U.S. Internal Revenue Service, October 1958.

Visiting Foreign Scholars

Leo H. Klaassen, Netherlands School of Economics, Rotterdam: visiting professor, Graduate School of Business Administration, University of California, Los Angeles, 1962.

Staffan B. Linder, Stockholm School of Economics: visiting associate professor, Columbia University, 1962-63.

Promotions

Robert E. Baldwin: professor of economics, University of California, Los Angeles.

Jacob Birnberg: assistant professor of accounting, Graduate School of Business, University of Chicago.

Morris Bornstein: associate professor of economics, University of Michigan.

Paul G. Craig: professor, department of economics, Ohio State University.

John Dearden: associate professor of business administration, Harvard University Graduate School of Business Administration.

Marion H. Gillim: professor of economics, Barnard College, Columbia University.

Frank H. Golay: professor of economics, Cornell University.

Jack Hirschleifer: professor of economics, University of California, Los Angeles.

John B. Lansing: professor of economics, University of Michigan.

Harvey J. Levin: professor of economics, Hofstra College.

Robert Lindsay: senior economist, Federal Reserve Bank of New York.

Arthur D. Lynn: professor of economics and assistant dean, College of Commerce and Administration, Ohio State University.

Martin V. Marshall: professor of business administration, Harvard University Graduate School of Business Administration.

Ilse Mintz: associate professor of economics, Columbia University.

J. Russell Nelson: assistant professor of finance, University of Minnesota.

Clinton V. Oster: professor, department of economics, Ohio State University.

Stephen W. Rousseas: associate professor of economics, Cornell University.

Warren J. Samuels: associate professor of economics, University of Miami School of Business Administration.

Irving Schweiger: professor of marketing, Graduate School of Business, University of Chicago.

Stanley J. Shapiro: assistant professor of marketing, Wharton School of Finance and Commerce, University of Pennsylvania.

Charles W. Skinner: associate professor of business administration, Harvard University Graduate School of Business Administration.

Leon Smolinski: associate professor of economics, Boston College.

Arthur N. Turner: associate professor of business administration, Harvard University Graduate School of Business Administration.

Paul A. Vatter: associate professor of business administration, Harvard University Graduate School of Business Administration.

Harry J. Wheaton: associate professor, School of Business Administration, The American University.

Stephen T. Worland: associate professor, department of economics, University of Notre Dame.

Administrative Appointments

Vernon R. Alden: president, Ohio University.

A. V. Berger-Voesendorf: chief, economic analysis, U.S. Army Corps of Engineers, Portland, Oregon.

Blanche Bernstein: officer in charge, Social Affairs, Office of International Economic and Social Affairs, International Organization, U.S. Department of State.

W. Donald Bowles: associate professor and chairman of the department of economics, American University.

Arthur Bronwell: dean of engineering, University of Connecticut.

Alpha C. Chiang: chairman, department of economics, Denison University.

Benjamin Chinitz: chairman and professor, department of economics, University of Pittsburgh.

Walter H. Delaplane: vice president for academic affairs, University of Arizona.

William Haber: chairman, department of economics, University of Michigan.

John Hein: chief, foreign research division, research department, Federal Reserve Bank of New York.

Werner Z. Hirsch: director, Institute for Urban and Regional Studies, Washington University.

Walter E. Hoadley: chairman of the board of the Federal Reserve Bank of Philadelphia.

Dick Leabo: associate dean, University of Michigan Graduate School of Business Administration.

Robert Lekachman: chairman, department of economics, Barnard College, Columbia University.

William H. Miernyk: professor of economics and director of the Bureau of Economic Research, University of Colorado.

G. Warren Nutter: chairman, department of economics, University of Virginia.

Alan T. Peacock: chairman and first professor of economics at newly created University of York, England.

A. Peter Ruderman: economic and reports officer in charge of the Evaluation and Reports Office, Pan American Sanitary Bureau.

A. E. Safarian: professor of economics and chairman, department of economics and political science, University of Saskatchewan.

G. R. Simonson: chairman, department of economics, Long Beach State College.

Harry W. Zimmermann: director, List Institute, Basle, Switzerland.

Appointments

Elliott L. Atamian: associate professor of finance, University of Miami School of Business Administration.

Edward C. Atwood, Jr.: professor of economics, School of Commerce and Administration, Washington and Lee University.

Jarvis M. Babcock: assistant professor of economics, University of Michigan.

Ralph E. Beals: assistant professor of economics, Amherst College.

Arthur Benavie: assistant professor of economics, Princeton University.

James P. Bennett: instructor in economics, University of Michigan.

Gerald O. Bierwag: instructor, University of Oregon.

Michael D. Bird: instructor in economics, University of Michigan.

J. O. Blackburn: assistant professor, department of economics and business administration, Duke University.

Jack Blinksilver: visiting lecturer on business administration, Harvard University Graduate School of Business Administration.

John Bottum: assistant professor, department of agricultural economics, Ohio State University.

Henry J. Bruton: associate professor, department of economics, Williams College.

Resignations

Anthony Downs, University of Chicago.

William D. Hopper, University of Chicago.

Charles M. Tiebout, University of California, Los Angeles.

VACANCIES AND APPLICATIONS

The Association is glad to render service to applicants who wish to make known their availability for positions in the field of economics and to administrative officers of colleges and universities and to others who are seeking to fill vacancies.

The officers of the Association take no responsibility for making a selection among the applicants or following up the results. The Secretary's Office will merely afford a central point for clearing inquiries; and the *Review* will publish in this section brief description of vacancies announced and of applications submitted (with necessary editorial changes). Since the Association has no other way of knowing whether or not this section is performing a real service, the Secretary would appreciate receiving notification of appointments made as a result of these announcements. It is optional with those submitting such announcements to publish name and address or to use a key number. Deadlines for the four issues of the *Review* are February 1, May 1, August 1, and November 1.

Communications should be addressed to: The Secretary, American Economic Association, Northwestern University, Evanston, Illinois.

Vacancies

Labor economists: Department of Labor has openings for work in the fields of wages, manpower, employment, labor and industrial labor conditions and related fields. Salaries range from \$6,435 to \$13,730 depending upon experience and training. To apply, send résumé or Standard Form 57 to the Executive Secretary, Board of U.S. Civil Service Examiners, U.S. Department of Labor, Washington 25, D.C.

Industrial organization, trade regulation, industrial concentration, structure of industry, price behavior: The Antitrust Division of the U.S. Department of Justice has openings for economists in Washington, D.C. Candidates should possess a background of education or experience in above fields. Duties involve the application of economic analysis to the enforcement of the antitrust laws. All positions are within the competitive civil service; entrance salaries range from \$5,355 to \$10,635 per annum. Write: Mr. John W. Adler, Chief, Personnel Office, Department of Justice, Washington 25, D.C.

Agricultural economist: Production economics research; rank and salary determined by education and research but range of \$8,500-\$11,000 possible. Short-term applicants unwanted. Supply information required in Federal Form No. 57. Interested parties apply Director, Land Study Bureau, University of Hawaii, Honolulu 14, Hawaii.

Technical assistant: For its program of technical assistant to the developing countries, the I.L.O. is looking for experts in the formulation and implementation of employment objectives in economic development to be assigned by the I.L.O. to serve as a member either (1) of the staff of a regional economic development institute to be set up in Latin America and later to be set up in Asia and Africa; or (2) of a group of experts advising a government on economic development planning and programming; or a combination of these functions. For details write to the Washington Branch Office, International Labor Office, 917 15th Street, N.W., Washington 5, D.C.

Economics: Assistant professor in economics. New England state college, about 3,700 students. B.A., B.S., and M.A. degrees. Beginning salary \$7,280 for ten months with additional compensation for six weeks summer session. Begin September, 1962.

Economics: Midwestern municipal university has full-time opening for an instructor; must be Ph.D. or near; expected to teach introductory courses plus some advanced undergraduate courses; labor economics background preferred but not essential; specialization and research not as important as good teaching ability; salary, with Ph.D., \$6,000 to \$6,900, depending on background, starting September, 1962.

P252

Business analyst: By a long-range planning group in a large oil producing and marketing organization, with responsibility for developing marketing innovations and planning diversification activities. Position is primarily concerned with the development and analysis of financial, economic, and marketing data as they relate to the profitability of proposed projects. Applicants should be proficient in at least three of the following areas: financial analysis, economic analysis, marketing research and statistical techniques, managerial accounting, and industrial engineering. A proven record of analytical ability is essential. Candidate should have an M.B.A. degree and five years of experience in the areas mentioned above. Salary will be commensurate with demonstrated ability. Covering letter outlining relative experience and current salary should accompany a detailed résumé. All replies will be treated with strictest confidence.

P257

Economics: University teaching appointment in Latin America. Prerequisites: graduate of an accredited college with major in economics and emphasis in the labor field; experience in industry or trade union desirable; prefer applicant working toward advanced degree; native fluency in Spanish; amenable in social situations. Job description: two-year contract on staff of economics department in Latin-American university. Starting salary, \$7,500 to \$8,500, plus allowances, depending upon qualifications. Send résumé.

P258

Economics: Ph.D., or all work completed except thesis, to take charge of area of economics. Rank, associate professor; salary according to education and experience. Write: Dr. T. Hillard Cox, Division of Business Administration and Economics, University of San Diego, San Diego, California.

Regional economics: Ph.D. or M.S. plus four years of research experience. Conduct fundamental and applied research on interdisciplinary problems in fields of regional development and long-range planning. Research on domestic and foreign areas using team approach. Send résumé of education and experience in research to L. G. Hill, Battelle Memorial Institute, 505 King Avenue, Columbus 1, Ohio.

Transportation economics: Ph.D. or M.S. plus four years of research experience. Conduct fundamental and applied research on domestic and foreign problems using interdisciplinary team approach. Send résumé of education and research experience to Battelle Memorial Institute (address above).

Economic planning: Ph.D. or M.S. plus four years of research experience. Conduct fundamental and applied research on area aspects of domestic and foreign problems using interdisciplinary team approach. Send résumé of education and research experience to Battelle Memorial Institute (address above).

Economics: Ph.D. with deep interest in economic research. Position involves analysis of interrelationships between technical developments and the economic environment. The effort includes fundamental research in economics, macroeconomic analysis as an input to long-range planning, and interdisciplinary studies of the sociopolitical implications of the economic impact of changing technology. The ability to communicate in an interdisciplinary atmosphere is essential. Desired detailed résumé of education, experience, and interests (Battelle Memorial Institute; address above).

Economics: Applications are invited for a Lectureship or Senior Lectureship in Economics at the University of New England, Australia. Post involves undergraduate teaching in economic theory and/or money and banking, and research in fields of appointee's own interest. The normal teaching load is about four class hours per week. The Department is of moderate size, at present 12 faculty members. Salary scale for Senior Lecturer: £A2,597 by £A95 to £A3,047; for Lecturer: £A1,777 by £A105 to

£A2,482. Status and initial salary according to qualifications and experience. Fare to Australia paid for appointee, wife, and children, plus a baggage allowance. Appointment may be permanent or for three years. In the latter case, £A400 will be paid toward return fares. Further information obtainable from Professor of Economics, University of New England, Armidale, N.S.W., Australia.

Economist: To assess and evaluate economic programs, offer consultative services and recommend economical goals for the state of Hawaii government. Requires Ph.D. in economics and at least 5 years of professional experience as research director, consultant or economist. Salary: \$11,064 to \$14,112. Contact: Department of Personnel Services, 825 Mililani Street, Honolulu, Hawaii.

Economist: Ph.D. qualified in micro theory and national income. Must also be willing to teach principles. Classes under 40. Excellent retirement and disability program. Salary: \$8,460 for qualified Ph.D. with some experience; \$7,200 for M.A. with substantial progress toward Ph.D. and some experience. Salaries quoted are for nine months. Permanent, beginning September, 1962. Send application to: Dr. H. F. Heller, Vice-President, Eastern Illinois University, Charleston, Illinois.

Economics: West Liberty State College, West Liberty, West Virginia, has a vacancy for an economics teacher. Should be able to teach all economic courses from principles to comparative. M.A. required; Ph.D. preferred. Rank and salary dependent upon qualifications and experience. Liberal fringe benefits, congenial atmosphere. Salary scale available upon request.

Economics and business administration: Opening for (1) a man with Ph.D. in economics; specialization in one or two of the following fields: labor, economic history, economic thought; (2) a man with an advanced degree in business administration. Teaching and business experience preferred. Rank and salary according to education and experience. Pension, group life, and medical plans. Appointments tenable from September 1, 1962. Please submit complete résumé including salary. Write: Francis J. Hayes, Economics Department, Loyola College, Montreal, Canada.

Marketing consultant: American foundation offers assignment, minimum of two years, in India. At least 15 years of experience in both business and teaching essential. Candidate must be a recognized authority in marketing and be familiar with international research in this field. Position requires ability to conduct seminars in marketing subjects, prepare course material and case studies, conduct field investigations and undertake marketing research studies. Salary range from \$12,000 to \$18,000 depending on qualifications. Furnished housing, auto, transportation, insurance, retirement and other benefits for employee and family also provided. Candidates will be interviewed in June and must be available prior to November, 1962. P259

Economists Available for Positions

The Macmillan Company

A special price of \$3.80 net, plus 12 cents postage, has been arranged in co-operation with The Macmillan Company for members of the American Economic Association. Purchases at the special rate may be made by placing an order with Dr. James Washington Bell, Secretary, American Economic Association, Northwestern University. A covering check, made out to The Macmillan Company, must accompany the order.

CARD DIALER TELEPHONE

TOUCH TONE PRINCESS TELEPHONE

There Is No End to Telephone Progress

PANEL TELEPHONE

Here are some of the new telephone instruments in various stages of development. Some are still experimental. Others are undergoing further work or being tested in use. They are symbols of other exciting things to come . . . to make your communication services even more attractive, useful and convenient.

This business has lived and grown successful by giving service.

It has done its best to give the public what it wanted, when it wanted it, with efficiency and courtesy. And then invented better things.

In the future, as in the past, the greatest progress will come through the combination of research, manu-

facture and operations in one organization, with close teamwork between all three . . . Bell Telephone Laboratories, Western Electric and the associated Bell telephone companies.

Wherever the trail may lead, on the earth or beneath the seas, in the air or through space, we will be trying very hard to serve you well.

Owned by more than two million Americans

ECONOMIC DEVELOPMENT IN PERSPECTIVE

By John Kenneth Galbraith. Knowing that new states and old states alike now recognize economic development as an imperative, Mr. Galbraith, United States Ambassador to India, delivered in late 1961 five public lectures on the essentials of the process. He felt that in the world-wide enthusiasm for economic minutiae there was a danger of mistaking parts of the problem for the whole. This book is the outgrowth of these talks. There is a wealth of clear sense here for the use of all countries, from those farthest along the road of economic development to those still at the beginning.

\$2.50

PRICES AND PRODUCTION OF MACHINERY IN THE SOVIET UNION, 1928-1958

By Richard Moorsteen. This study provides the key quantitative indicators for 30 years of Soviet experience in developing machinery production: indexes of changes in price levels, of changes in output, and of the supply machinery for purposes of capital construction. The raw data and particulars of the calculations are reproduced in their entirety in eight appendixes; the volume contains 124 tables, a bibliography and a systematic index. *A RAND Corporation Study*

\$15.00

GERMANY AND THE DIPLOMACY OF THE FINANCIAL CRISIS, 1931

By Edward W. Bennett. Documentation now available makes possible the first full investigation of the 1931 European crisis, the only one between the wars in which the United States took a leading role. Brüning's foreign policy is clarified, and the author shows how Germany sought to exploit her private debt to Wall Street, and how the Bank of England's Governor opposed French diplomacy.

\$7.50

THE GOSPEL OF WEALTH AND OTHER TIMELY ESSAYS

By Andrew Carnegie, edited by Edward C. Kirkland. Issued in 1900, Carnegie's essays illustrated the progressive businessman's concern with international affairs and American imperialism. His book provided perhaps the most influential social-economic justification for American capitalistic philanthropy.

A HISTORY OF THE BRITISH STEEL INDUSTRY

By J. C. Carr and Walter Taplin. This book presents changing industrial conditions in Britain and their contributory factors clearly and authoritatively. Included is a comprehensive account of the steel industry in Europe and the United States, providing a full background for the competitive and international aspects of the British industry. \$11.00

COLLECTIVE BARGAINING IN SWEDEN

By T. L. Johnston. No other book offers so thorough an analysis of the model European 'welfare state'. The first systematic study of Swedish policy for wages under full employment, the first major evaluation of the famous "Saltsjöbad agreements" and of the postwar movements towards industrial democracy. \$7.50

THE ECONOMY OF CYPRUS

By Albert J. Meyer with Simos Vassiliou. Cyprus' smallness, indigenous socio-economic structure, and British legacy—including detailed statistical records—make it a laboratory of Middle Eastern development. The authors have designed this brief analysis for the general reader aware of the importance of Cyprus for Europe, the United Nations, and the Atlantic Alliance. \$3.50

ENTREPRENEURS OF LEBANON

THE ROLE OF THE BUSINESS LEADER IN A DEVELOPING ECONOMY

By Yusif A. Sayigh. This is a striking portrait of the Lebanese business leader—his background, his economic mobility, his approach to policy decisions, his motives, and his reactions to the economic and political environment. Mr. Sayigh examines entrepreneurial theory as it applies to the underdeveloped world, and analyzes the role of the entrepreneur in the process of economic development.

THE PANIC OF 1819: Reactions and Policies

Murray N. Rothbard

The story of America's first severe depression and the remedies which were suggested for its control are presented by a noted research economist. Dr. Rothbard discusses the proposals for monetary expansion, the direct measures for debtors' relief, and the controversies over a protective tariff. An important book on a relatively neglected epoch in the economic history of America.

TWO IMPORTANT TITLES

PREFACE TO ECONOMETRICS

by Michael J. Brennan, Jr., Brown University

This book provides an introduction to quantitative methods that can be understood by the undergraduate. The text material is as nontechnical as possible within limits of precision and accuracy, especially in the early chapters. Each new subject is introduced gradually to give the student time to digest the new learnings before taking up additional ones. Emphasis is placed on applications of economic theory, quantitative measurement, and tests of correctness of theory. An extensive group of problems is included at the end of each chapter.

BUSINESS CYCLES AND FORECASTING

2nd Edition—By Carl A. Dauten, Washington University

Attention to current trends in education for business is reflected in this revision. This new book provides an analytical presentation of cycle theory, forecasting problems, and policies for economic stability. Alternate business cycle theories are presented without critique. Keynesian theories are analyzed and then used in the description of the cyclical processes. Six new chapters are included in the second edition.

Cincinnati 27 New Rochelle, N.Y. Chicago 44 Burlingame, Calif. Dallas 2

MONEY, BANKING, AND MONETARY POLICY

CLIFTON H. KREPS, Jr., *University of North Carolina*

This important new book affords the student a thorough understanding of the national economic significance of monetary and banking policy. Theory is woven throughout in a highly integrated approach to the essential principles of money and banking. Attention is thus focused on the "why" of institutional

processes rather than the "how." The analytical discussion of the history of money and banking development places in true perspective the complex issues of theory and policy. Book contains ample question, problem, and biographical materials. 1962. 607 pp. \$7.50

FUNDAMENTALS OF ECONOMICS

RUBY TURNER MORRIS, *Connecticut College*

Student oriented throughout, this highly readable textbook provides a broad background in economic theory and a detailed description of how the economic order operates. It offers a unified, balanced treatment of microeconomics and macroeconomics, supply and demand, monopoly, and pure competition; practical application of theory is stressed. The anal-

ysis is distinguished for its clarity; important interrelationships, analytical comparisons, historical references, and contemporary applications are emphasized. Hundreds of graphs and charts illustrate and focus the discussion. *Student Workbook and Instructor's Manual available.* 1961. 878 pp. \$7.00

ECONOMIC AND SOCIAL SECURITY—Second Edition

Public and Private Measures Against Economic Insecurity

JOHN G. TURNBULL and C. ARTHUR WILLIAMS, Jr., *both University of Minnesota; and EARL F. CHEIT, University of California, Berkeley*

Designed for students of social insurance and social security, this new book offers a thorough discussion of the various public and private measures for extending economic security. The emphasis is on principles and understanding; abstract discussion of statistical detail is avoided. Following the carefully planned and successful pattern established in the

original volume, the Second Edition retains the use of analytical tools in evaluating the private and social insurances and assistances involved in such problems as old age and death, occupational disability and non-occupational illness, unemployment, and sub-standard working conditions. *2nd Ed.*, 1962. 552 pp. \$8.00

MARKETING—Seventh Edition

THEODORE N. BECKMAN and WILLIAM R. DAVIDSON
—both *The Ohio State University*

This standard textbook provides a broad understanding and appreciation of the complete marketing process, its essential economic functions, and the institutions performing them. Giving proper emphasis to the managerial viewpoint, the Seventh Edition strengthens the social and economic coverage of marketing in all its significant implications. It includes

discussions of physical distribution, the significance of consumer-oriented marketing management, quantitative methods of analysis, and marketing aspects of the behavioral sciences. Ample question and problem material. *Instructor's Supplements available.* 1962. 873 pp., illus. \$8.00

Central Planning in Poland

by John Michael Montias

This book surveys, analyzes, and appraises the Polish experience with central planning in an institutional framework adapted from the Soviet model. Following a comprehensive introduction to the theory of central planning based on a comparison of administrative planning methods with input-output analysis and linear programming, Mr. Montias describes the postwar development of the economy and the organization of planning during the period of the Six-Year Plan. He devotes separate chapters to the planning of material balances, the programming of investments and long-range plans, and to fiscal and financial policy. The chapter on price formation contains detailed statistical information, some of it hitherto unpublished in Poland, and an exhaustive description of price-setting practice. The last two chapters are given over to the reforms in the management of the economy made by the Gomulka regime after 1956 and to the theoretical debate among Polish economists which formed the background of these institutional changes. Much of the information in the book was gathered from interviews with Polish officials and economists and from research undertaken in Warsaw, Krakow, and Wroclaw from 1956 to 1961 in the course of the author's frequent visits to Poland. *Yale Studies in Economics*, 13.

Economic Change in Rural India

Land Tenure and Reform in Uttar Pradesh, 1800-1955

by Walter C. Neale

A valuable contribution to our understanding of the problems of the underdeveloped countries, this carefully documented study traces the history of land tenure and land reform from 1800 to 1955 in Uttar Pradesh, a constituent state of India. Taking issue with the proponents of land reform as a panacea for poverty, Mr. Neale argues that land reform alone will not solve agricultural problems which stem from the vicious circle of underdevelopment and overpopulation and from attitudes embedded in a socio-religious hierarchy. He finds that the lot of the cultivator in Uttar Pradesh ultimately depends upon the injection of new capital and on the provision of alternative employment, with higher productivity. *Yale Studies in Economics*, 12.

THE STATISTICAL METHOD IN BUSINESS

By **FREDERICK A. EKEBLAD**, *Northwestern University*

The demand for men and women trained in statistics has grown greater with the growth of business education. The trained statistician needs a background in the techniques, the applications, and the philosophy of the statistical method. This book is designed to cover these needs. It is about the method in its applications to the problems of decision making in business. The author stresses the underlying philosophy of the statistical method and relates it to familiar experiences of the reader in addition to relating it to the problems of business.

The statistical method is treated as a unified whole rather than as a collection of miscellaneous techniques. Underlying this treatment is the problem of uncertainty. The role of probability concepts and methods pervades the whole book and is not restricted to a few chapters on sampling. This is accomplished by emphasizing the practicability of utilizing a definition of probability that associates it with the state of knowledge that a person has rather than with a set of abstract events. Randomness of events is associated with our ignorance of events rather than with a state of nature. In this way, it becomes possible to emphasize the techniques a person should use to best utilize the information he has about a situation. This approach also makes it possible to clarify the separate roles played by knowledge and technique in dealing with practical problems.

Important contributions are made in the linking of the traditional ideas of confidence intervals and hypothesis testing with some of the recent developments in decision theory and Bayesian statistics. An attempt is made to place the use of the statistical analysis of numerical data as a tool of problem solving in the larger context of all the sources of knowledge that a person has to aid in solving his problems.

The many problems that are appended to each chapter are designed to stimulate thinking on practical issues rather than as vehicles for routine calculation.

BOOKS

John Wiley & Sons and Longmans, Green of London are pleased to announce that the majority of Longmans' existing and future publications in Economics will now be distributed in the U.S., its Dependencies, and the Philippines by Wiley. The first list of Longmans' titles in Economics includes the following:

THE DEVELOPMENT OF ECONOMIC DOCTRINE

An Introductory Survey

By Sir Alexander Gray, University of Edinburgh

This book is a well-edited history of economic doctrine which is designed to serve as an introduction to the study of economics. The author has chosen to explicate the philosophies and opinions of a small but representative group of economic theorists in order to provide a complete picture of the scope of economic doctrine. The aim of the book is to provide the beginner with a background for the understanding of current economic thought by presenting the mainstream of past ideas which have influenced the economic trends of today. *384 pages. \$2.50.*

A TEXTBOOK OF ECONOMIC THEORY

Second Edition

*By Alfred W. Stonier, University College, London, and
Douglas C. Hague, University of Sheffield*

This book is a systematic, comprehensive introduction to economic theory, giving an outline of the way in which an economic system works. This analysis considers only the most important features of the modern economy. The authors present their material in two parts, the first dealing with price theory and the second with employment theory. The two significant changes in this edition are the rewriting of the first part of the section on Quasi-rent and the enlargement of the discussion of open-market operations. *513 pages. \$4.75.*

FORD FOUNDATION DISSERTATIONS

Leaders in business education are seriously concerned with improving the quality of research that underlies their field. A strategic step toward this goal is to emphasize the importance of doctoral dissertations of high quality prepared by graduate students in business administration. Another is to encourage able graduate students in the social sciences and fields such as mathematics and statistics to choose for their dissertations problems directly relevant to the practice of business or management.

This competition is intended to provide widespread professional recognition for those students whose doctoral research is not confined to careful description of current business practice but is distinguished by its analytical content and strong theoretical roots in the disciplines underlying the profession of business administration.

The dissertations selected will be published and widely distributed as examples of the best doctoral research being produced. Hopefully these will encourage the writing of other dissertations of equal or greater distinction.

1960-1961 Award Winners:

Portfolio Selection: A Simulation of Trust Investment. By Geoffrey P. E. Clarkson, School of Industrial Management, Massachusetts Institute of Technology

Financing and Initial Operations of New Firms. By George William Summers, College of Business Administration, Arizona State University

The Investment Decision Under Uncertainty: Portfolio Selection. By Donald E. Farrar, University of Wisconsin

An Evaluation of a Forced-Choice Differential Accuracy Approach to the Measurement of Supervisory Empathy. By Richard S. Hatch, USI Industrial Science Division, Goleta, California

The Term Structure of Interest Rates. By David Meiselman, Department of Economics, University of Chicago

1959-1960 Award Winners:

Marketing in an Underdeveloped Economy: The North Indian Sugar Industry. By Leon V. Hirsch, Graduate School of Business Administration, Harvard University

A Heuristic Program for Assembly Line Balancing. By Fred M. Tonge, Graduate School of Industrial Administration, Carnegie Institute of Technology

Decentralization of Authority in a Bureaucracy. By Bernard H. Baum, Department of Sociology, University of Chicago

The Distribution of Automobiles, An Economic Analysis of the Franchise System. By Bedros Peter Pashigian, Dept. of Economics, Massachusetts Institute of Technology

The Choice of Wage Comparisons. By Martin Patchen, The University of Michigan

1958-1959 Award Winners:

Computer Models of the Shoe, Leather, Hide Sequence. By Kalman J. Cohen, Graduate School of Industrial Administration, Carnegie Institute of Technology

The Structure of a Retail Market and the Market Behavior of Retail Units. By Robert R. Holdren, Iowa State University of Science and Technology

Polya-Type Distributions in Renewal Theory, with an Application to an Inventory Problem. By Frank Proschan, Research Specialist, Boeing Scientific Research Laboratories, Seattle, Washington

Budget Control and Cost Behavior. By Andrew C. Stedry, Massachusetts Institute of Technology

Some Personality Determinants of the Effects of Participation. By Victor H. Vroom, Department of Psychology, University of Pennsylvania

Special educational price available for teachers, students, and educational libraries—\$1.00 per copy on PREPAID ORDERS ONLY.

The below-cost price of \$1.00 per copy is made possible by the Ford Foundation subsidizing publication of the dissertations, and Prentice-Hall contributing its publishing facilities and services, to achieve maximum distribution of these dissertations to teachers and students.

Orders that are not prepaid will be billed at \$4.50 per copy. This price is also applicable to the general public.

THE AMERICAN ECONOMY

by Betty G. Fishman and Leo Fishman
both at West Virginia University

This introductory textbook presents, in accurate and readable form, basic information about the nature of the American economy, the economic problems which are important today, and the principal tools which can be used in analyzing, solving, or ameliorating these problems and evaluating the results.

Each collaborator was selected on the basis of his special competence in a particular field and unlike some multi-author texts, **THE AMERICAN ECONOMY** is characterized by a logical progression and an integration of subject matter, concepts and statistics.

844 pages, \$7.95

With the collaboration of:

Jules Backman
Arthur R. Burns
Eugene Clark
Joel B. Dirlam
Margaret Greenfield
William F. Hellmuth
Raymond F. Mikesell
Harlow D. Osborne
Gerald G. Somers
Marshall D. Wattles

WORKBOOK to accompany **THE AMERICAN ECONOMY**

The workbook is divided into seven parts which are subdivided into four sections:

1. An outline of the correspondingly numbered chapter in the text.
2. A list of important terms and concepts introduced and used in the text chapter.
3. A series of true-false questions.
4. Essay questions and (in appropriate cases) some problems. 263 pages, \$2.95

INTERNATIONAL ECONOMICS

by Hugh B. Killough,
Northeastern University
Lucy W. Killough,
Wellesley College

In this new text, the principles of international economics are analyzed against a background of their historical development in order to demonstrate how these principles have evolved. At every turn, however, the authors emphasize the current usefulness of economic theory in clarifying present-day issues and solving present-day problems.

NEW SPRING PUBLICATIONS

THE MAKING OF ECONOMIC SOCIETY

by Robert L. Heilbroner

Robert L. Heilbroner's book offers a new approach to economics. In vivid prose and swift narrative style, he has set forth the basic elements of economic thought in a context at once dramatic and meaningful—the context of history. But Heilbroner has aimed higher than an introduction to economic history. As the reader retraces the sweep of economic evolution, from slave systems and feudalism down through the Industrial Revolution to the present, he is introduced to the essentials of economic theory as the key by which economic history must be understood. Thus history and theory mutually illuminate one another, each rendering the other more significant and intellectually exciting.

Heilbroner has not attempted to supplant the standard text. Although *The Making of Economic Society* presents the main outlines of economics in carefully organized fashion, it is intended primarily as a stimulus for more formal study, particularly in the case of economics majors. Few readers, however, will fail to benefit from the lucid exposition of fundamental economic ideas or from their brilliantly revealed relevance to economic issues, past and present.

MULTILATERAL BALANCING IN INTERNATIONAL TRADE

By MICHAEL MICHAELY*

The purpose of this paper is to present a quantitative analysis of the extent of multilateral balancing in international trade. Problems involved in measuring multilateral balancing, as well as the scope and method of the study, will be indicated in the first section. The following section will contain the study's basic findings, along with observations on the development of multilateral balancing over time and on its magnitude within blocs of countries. In the third section the discussion will turn to the attributes of countries whose trade is highly multilateral, and to the role of specific countries as "agents" of multilateral balancing in world trade.

I. Concepts and Method of Measurement

The concepts of "bilateral balancing" and "multilateral balancing" are used in the present study to refer in each case to a certain attribute of the geographic distribution of a country's trade, and not to indicate a certain policy pursued by the country. Thus, a country may be termed "highly bilateral" even though its government is as far as possible from following bilateral policies—and vice versa.¹

*The author is lecturer in economics at the Eliezer Kaplan School of Economics and Social Sciences, Hebrew University of Jerusalem. This study was undertaken during his stay at the University of Chicago, which was made possible by the University's postdoctoral fellowship in political economy and by a research grant from the Rockefeller Foundation. Harry G. Johnson and Simon Kuznets have contributed helpful comments and suggestions.

¹It should also be stated, to prevent misunderstandings, that terms like "the country directs its exports" or "the country is interested in certain imports" do not purport to convey the impression that it is the government which "directs" exports, or that the "interest" is that of the government or is otherwise expressed in some centralized, collective form. These terms and others like them are shorthand descriptions of situations that are usually determined by separate actions of all economic units within the country.

As long as international economic transactions consist purely of exchange of goods among nations, the distinction between "bilateral balancing" and "multilateral balancing" is simple indeed. A transaction in which country A exports goods to country B in exchange for other goods which it imports from B is bilaterally balanced. When, on the other hand, the proceeds of A's exports to B are used to finance imports from country C to country A, the (combined) transaction is multilaterally balanced.

The introduction of trade in services does not create any conceptual difficulty: exports and imports of services are identical, in this respect, with exports and imports of goods. Services may be exchanged against goods or against other services in a transaction which is either bilaterally or multilaterally balanced. Trade in services presents, however, a major practical obstacle to the measurement of multilateral balancing: while information on the geographic distribution of trade in goods is available for almost all countries and for long periods of time, and is usually quite reliable, data on the geographic distribution of trade in services are meager and of a doubtful quality. For this reason, trade in services is excluded from the present study altogether. This leads probably to many errors; transactions that appear as multilaterally balanced when trade in services is abstracted from may in fact be bilaterally balanced, and vice versa. It is hoped, however, that the errors involved are not large enough to invalidate the results of the study, since in most countries the trade in services is small relative to the size of trade in goods.

The existence of international capital movements, on the other hand, constitutes a conceptual as well as a practical challenge to the measurement of multilateral balancing. To be sure, some capital movement must be involved in most international transactions in goods—and *a fortiori* in multilateral transactions. In the example above, country A does not actually acquire, in exchange for the goods which it exports to B, either goods from B or from C. It will usually acquire, instead, short-term financial assets in B, which may be used later to pay for imports from B or from C. But suppose that by the end of the period of reference (say, the calendar year) these assets have not been used at all. There is no way to tell whether they will be used in the future to buy goods in B or C. (Indeed, it is even impossible to assert that these assets will be liquidated at any time in the future!) In the same way, when A finances imports from B by running down short-term assets in B outstanding at the beginning of the period of reference, one cannot tell whether these assets had been acquired by sales of goods to B or to C. One cannot, therefore, term these transactions as either "bilateral" or "multilateral."

Consider now long-term capital transfers. Suppose country A borrows from country B, and uses the proceeds to finance imports from the lending country. The exchange in this case is not of goods for other goods but of goods for financial assets. One could extend the terms "bilateral balancing" and "multilateral balancing" to call a transaction of this nature "bilateral," or to call it "multilateral" when the proceeds of B's loan to A are used to finance A's imports from C. In the present study a narrower definition of "bilateral balancing" and "multilateral balancing" is adopted: the terms will apply only to international *trade*, that is, to the exchange of goods (and conceptually, but not in practice, also of services) for other goods (and services), and not to international transactions where goods are exchanged for financial assets. Besides the conceptual difficulties leading to this choice of terms, it is also dictated by overwhelming pragmatic reasons. A measurement of multilateral balancing when this term is interpreted more broadly would require data on the geographic distribution of capital transfers from and to each country, which are usually unavailable and whose reliability may often be doubted even when they do exist.²

This definition of the terms leads to an exclusion from the coverage of this study of all countries which maintain consistently large import or export surpluses;³ it is obvious that a large fraction of international transactions of these economies consists of the exchange of goods for financial assets. It will be assumed, on the other hand, that where exports and imports are roughly equal, that is, when no *net* capital transfers to or from the country take place, *gross* capital movements (in opposite directions and balancing each other) are also absent. This amounts to an assumption that an approximate equality of exports and imports implies the absence of transactions in which goods are exchanged for financial assets, so that in countries maintaining this equality "multilateral balancing," in the narrow sense adopted in this study, may be measured.⁴

It is probably clear, but should nevertheless be stated, that one cannot trace individual transactions (except when these take the form of barter trade). The exporter from A to B, to repeat, acquires short-term

² The data on capital transfers would also have to distinguish between long- and short-term capital movements. A particularly baffling problem of principle would be presented by unilateral transfers (gifts, grants, donations or reparations). Here no transaction exists at all, in the ordinary sense of this word. The concepts of "bilateral balancing" and "multilateral balancing" would have to be stretched even further to include transfers of this nature.

³ A surplus of imports over exports, or vice versa, is considered "large" for the purpose on hand when one of these magnitudes exceeds the other by over 50 per cent. While a few countries are thus disqualified on account of maintaining large import surpluses, only one country—Venezuela—is excluded from the study for having large export surpluses.

⁴ It is gross rather than net movements of capital which are of interest in this context.

financial assets in B; he will normally sell these assets to some bank in A, and it would be impossible—and immaterial—to know whether these specific proceeds will be used to pay for imports from B or from C. Instead of following individual transactions, one should consider aggregates of transactions during a period of reference, which in the present study will be a calendar year.

The index which will measure the degree of multilateral balancing in a country's trade, to be denoted for each country j by T_j , is the following:

$$(1) \quad T_j = 100 \frac{\sum_s \left| \frac{X_{sj}}{X_{.j}} - \frac{M_{sj}}{M_{.j}} \right|}{2}$$

where X_{sj} stands for exports of country j to any country s , during the year, $X_{.j}$ stands for country j 's total exports, M_{sj} for country j 's imports from country s , and $M_{.j}$ for j 's total imports—all terms being value magnitudes and all (or at least each pair in the numerator's fractions) denoted in the same currency. The differences whose sum constitutes the numerator are measured by their absolute magnitudes, regardless of sign. For convenience, the index is put in percentage form. It expresses the share of the country's trade which is conducted on a multilateral basis. The potential range of the index is from zero to 100. It will be zero when the proportion of each foreign country's share in country j 's exports is equal to the proportion of that country's share in j 's imports; this is defined as perfect bilateral balancing. The index will be 100, on the other hand, when the country in question buys nothing in countries to which it exports—and, of course, vice versa; this is defined as perfect multilateral balancing.⁵

The period with which the study is mainly concerned is the postwar

This may be demonstrated by an example of an extreme situation. Suppose that country A's trade during the period of reference looks as follows:

	<i>A's Exports to:</i>	<i>A's Imports from:</i>
Country B	100	—
Country C	—	100
	—	—
World	100	100

On this evidence alone, A appears to practice perfect multilateral balancing. Suppose, however, that long-term capital movements, of the size of 100 units each, take place from A to B and from C to A during the period. By the broad definition of multilateral balancing, which takes into account exchange of goods for financial assets, A's economic transactions would be termed perfectly bilateral. The narrower definition of the concept of multilateral balancing which is used in this study does not enable the derivation of any conclusions about the extent of multilateral balancing in A.

⁵ A somewhat different index was used in measurements of multilateral trade done by

one. For obvious reasons, measurements of multilateral balancing could not be carried out for each single year of this period. Instead, a sample of three years has been selected: 1948, 1954 and 1958—the latest year for which data were available when the study was carried out. For the sake of comparison, indexes of multilateral balancing have also been constructed for 1938, the last prewar year.

While in principle the study should have covered all the world's countries and territories, data for some were not available. Likewise, it was felt that the investigation of some of the smallest (in terms of size of international trade) territories may not be rewarding, and might make the presentation of the study's findings too cumbersome. It should also be recalled that a few countries disqualify for the study on account of their large export or import surpluses.⁶ The study covers in effect 65 countries and territories (for some of which measurements of multilateral balancing for 1938 and/or 1948 could not be carried out for lack of data). Five of these countries belong to the Soviet bloc, and while neither the total value of their trade nor that of the bloc as a whole is known, the trade of the five presumably constitutes the major portion of the bloc's foreign trade. The combined trade of the other 60 countries amounts to around 90 per cent of the trade in goods in the non-Soviet world. Despite the few omissions, therefore, the study comprehends an overwhelming majority of the world's international trade.

II. *The Extent of Multilateral Balancing*

The indexes of multilateral balancing are presented in Table 1. The three averages which appear at the bottom of the table are: (1) an unweighted average index of multilateral balancing for the 65 countries; (2) an unweighted average for 60 countries only, excluding the five

the League of Nations [6, 1933, p. 60]. In symbolic terms, using the notation of the text, the League of Nations' index is

$$\frac{\sum_s |X_{sj} - M_{sj}|}{X_{.j} + M_{.j} - |X_{.j} - M_{.j}|}$$

⁶In addition to the grounds for exclusion of countries from the scope of this study given in the text, it was deemed misleading to include countries which to a large extent send their exports or receive their imports through intermediate countries in which, in turn, these constitute only a transit trade. For that reason the study does not include Paraguay, which carries a large portion of its trade with the outside world through Argentina. Transit trade may be included, though, in the trade records of other countries, and the lack of ability to distinguish it from "genuine" trade may contribute to errors in the indexes of multilateral balancing.

Norway, a country with a large import surplus on merchandise account which is offset mainly by a surplus on services account rather than on capital account is included in the study. Lack of information on the geographical distribution of trade in services should subject the index of multilateral balancing of Norway to much higher margins of error than the indexes of most other countries.

Source: Data from [9] [8] and [5].

* In constructing the index of multilateral balancing of a country, exports or imports to countries which individually constituted very small fractions of the total exports or imports of the country in question were disregarded. The trade excluded in this way amounts usually to around 5 per cent and rarely reaches 10 per cent or more of the total trade of the country.

Weighted average, non-Soviet countries	27.5	30.8	23.9	22.4	

Soviet countries; this is provided for comparison with (3) a weighted average for these 60 countries, where the proportion of each country's exports in world exports serves as the weight of the country's index. The five Soviet countries are excluded here for lack of data on the absolute size of their trade in comparison with the trade data available for other nations.

The rise of multilateral balancing from 1938 to 1948, which appears from Table 1, and even more the decline of multilateral balancing between 1948 and later postwar years, seem surprising. The early postwar period was distinguished by extreme bilateral trade policies in many countries, certainly in comparison with the policies followed in later years. I suspect that the 1948 indexes of multilateral balancing are indeed misleading for many countries, so that trends supposedly revealed by them may be doubted. The reason is that in 1948, as in other early postwar years, international transfers of capital were unusually large in relation to the size of international trade; this is true both for the world as a whole and for many individual countries. Although, we recall, countries with a consistently high gap between the volumes of exports and imports are not within the confines of this study, the in-

vestigation does include some countries that show large import (and, in a few cases, export) surpluses in 1948, a fact which—as has been argued earlier—detracts from the validity of the indexes of multilateral balancing for these economies. Germany provides probably the most outstanding example for the operation of this factor.

It may be advisable, therefore, not to pay overdue attention to the trends supposedly established by the indexes for 1948. But two other phenomena revealed by the findings of Table 1—the decline of the level of multilateral balancing from 1938 to the late postwar period, and the relative stability, or even slight decline, between 1954 and 1958—also do not seem to conform with what might have been expected on the basis of our general knowledge of foreign-trade policies followed in the last few decades. The late 'thirties are usually considered a period of highly restrictive, highly bilateral trade policies—certainly more so than the middle and late 'fifties. Yet a lower level of multilateral balancing is found in recent years than in 1938. Even when attention is confined to non-Soviet European countries, where bilateral policies were widely practiced in the 'thirties but have been out of fashion in recent years, it appears that the level of multilateral balancing changed between the periods under consideration only little in most countries, and in both directions. Most surprising, probably, is the situation in Germany: in this stronghold of restrictive bilateral trade policies before the war, and of free, multilateral trade policies in the 'fifties, the level of multilateral balancing seems to have actually declined between 1938 and 1954-58.

It is also odd that the level of multilateral balancing did not change—or even declined slightly, if judged by the weighted averages—between 1954 and 1958. Although 1954 was a year of nearly “normal” trade, controls over foreign trade, which almost inevitably lead to bilateral policies, had certainly been more widespread at that time than in 1958. Apparently, this change does not find its reflection in the indexes of multilateral balancing. A tentative conclusion that may be drawn from this fact, as well as from the comparisons of 1954-58 with 1938, is that foreign-trade policies followed by governments probably have a weak effect on the level of multilateral balancing in comparison with other forces which participate in determining this level.

That in general the factors leading to bilateral balancing of trade are indeed potent can scarcely be doubted. Only in very few countries does multilateral trade usually constitute over half of the country's total trade, according to the indexes presented in Table 1; and although these indexes cannot, due to the deficiencies inherent in them, claim to be precise measurements of the degree of multilateral balancing, it is unlikely that they could deviate so much from the “true” measures as

to falsify considerably the over-all picture. The weighted average index of multilateral balancing is probably close to the true share of multilateral trade in total world trade. This share thus appears to be, for the non-Soviet world, around 28 per cent in 1938, 24 per cent in 1954, and 22 per cent in 1958.⁷

An examination of the indexes of multilateral balancing for individual countries will show large fluctuations in their relative positions. Only a few countries will be found with a consistently high or a consistently low level of multilateral balancing in all four years of observation. Profound changes in the geographic structure of trade which took place during the war and the early postwar years—as well as the afore-mentioned “distortions” of the indexes of multilateral balancing in 1948 by large-scale capital transfers—are responsible for these fluctuations. A close resemblance is found, on the other hand, between the relative positions of countries in 1954 and in 1958. By 1954 the trade of most countries had already become “normal,” and changes in its geographic distribution, as well as in others of its characteristics, have been slow since. In particular, the pattern of the geographic distribution of export and import surpluses, of which the index of multilateral balancing is an

⁷The measurement of multilateral balancing in the early 'thirties carried out by the League of Nations [6] appears to show an even lower degree of multilateralism. These studies are based on the trade of 22 countries, representing about 70 per cent of world trade. The method used was first to divide all trade into three groups: (I) bilateral merchandise trade; (II) balances of total merchandise trade; and (III) triangular merchandise trade. The proportions of these three groups in total trade are (in per cent):

	1929	1931	1932	1933	1934	1935
I	71.7	68.1	69.4	71.3	71.9	74.2
II	9.9	16.4	15.6	14.4	13.0	12.0
III	18.4	15.5	15.0	14.3	15.1	13.8

The first group represents clearly bilateral trade, and the third group multilateral trade, while the nature of the second group cannot be determined. The ratio of the third group to the first and third, which is the index of multilateral balancing described earlier in footnote 5 (it was actually used by the League of Nations only in the 1933 *Review*) is as follows:

1929	1931	1932	1933	1934	1935
20.3	18.5	17.5	16.6	17.4	15.7

Probably on the strength of these measurements, Folke Hilgerdt estimated that “about 70% of the world's merchandize trade consists of the mutual and balancing exchange of goods” [2, p. 176]; but that of the remaining 30 per cent about one-third represents a bilateral exchange of goods for services (among which Hilgerdt mentioned specifically only “the yield of foreign investment,” that is, capital services), so that the truly multilateral trade comes to about 20 per cent of world trade. This adjustment for bilateral exchange of goods for services does not strike me as fully legitimate: any adjustment of this nature should require the introduction of *all* trade in services, whether they are exchanged for goods or for other services, and whether the trade in them is bilateral or multilateral.

It should be noted that the twenty-two countries covered by the League of Nations' studies include a much stronger representation of highly bilateral (in those years) than of highly multilateral economies.

expression, has changed substantially since 1954 only in a small number of countries. Thus, in deriving conclusions about multilateralism in various countries, we shall focus our attention in the rest of this study on the late postwar period, and confine our observations to 1954 and 1958, neglecting the earlier years.

To begin with, the large degree of resemblance in the relative level of multilateral balancing of countries in 1954 and 1958 renders it permissible to regard an average of the indexes in the two years, for each country, as representing the country's level of multilateral balancing in recent years. These average indexes for 1954 and 1958 are shown in

TABLE 2—INDEX OF MULTILATERAL BALANCING BY
MONETARY-GEOGRAPHIC AREAS, 1954-58

Area	Mean	Weighted Average
United States and Canada	17.1	16.9
Latin America—Dollar Countries	23.1	18.7
Latin America—Nondollar Countries	38.0	35.1
United Kingdom	18.9	18.9
Overseas Sterling Area	36.0	34.9
Continental Western Europe ^a	22.8	22.3
Eastern Europe	9.5	..
Rest of the World	31.3	35.2

^a Including Continental OEEC countries, Spain, Finland, and Yugoslavia.

the last column of Table 1; countries are arranged in the table in descending order of the level of these indexes.

The large number of countries covered by the analysis does not enable a separate investigation of each single country. It is possible, however, to examine the positions of large groups of countries. In Table 2, derived from the preceding table, indexes of multilateral balancing are shown for eight geographic or monetary areas, most frequently used in studies of the postwar world, into which the 65 countries are divided.

It is certainly not surprising to find that Soviet Eastern Europe has the highest level by far of bilateral balancing in international trade. In fact, no single country outside this bloc—Mexico being a borderline case—has an index of multilateral balancing as low as that of any country within the Soviet bloc. Bilateral trade forms as high as 90 per cent, sometimes even more, of the trade of Soviet countries. It is interesting to observe, from Table 1, that the central nation in the Soviet area, the USSR, which in distinction from the other four countries in the area had had the same political-economic regime in 1938 as in 1954-58, nevertheless shows a considerably higher level of multilateral balancing in its trade in 1938 than in recent years. The reason for this is un-

doubtedly the fact that whatever foreign trade was transacted by the USSR before the war was conducted, presumably in convertible currencies, mainly with countries less inclined towards bilateral trade policies than the USSR itself. Since the war, on the other hand, and the establishment of a Communist bloc, most of the foreign trade of the USSR has been diverted to countries within this bloc, all of whom follow bilateral trade policies similar to those of the USSR itself. The differences in this respect between Soviet and other countries are indeed so conspicuous—and for such obvious reasons—that it seems preferable to exclude the former from any international comparisons. Thus, when a country is termed in this study “highly bilateral,” this should be understood to be based only on comparisons with non-Soviet countries.

Among the other areas, one may distinguish two groups. In one, including the nondollar countries in Latin America, the Overseas Sterling Area, and the Rest of the World, the level of multilateral balancing is relatively high: around 35 per cent of total foreign trade is conducted in a multilateral form. The other group, including the United States and Canada, dollar countries in Latin America, the United Kingdom, and Continental Western Europe, is relatively bilateral: in these areas, multilateral trade forms only about 20 per cent of total foreign trade.

By and large, countries in the former group followed, in the period under consideration, more restrictive, bilateral trade policies than countries in the latter group, whose trade in this period was largely free and was conducted overwhelmingly in fully- or semiconvertible currencies. It does not follow, of course, that countries in the former group would not have realized a still higher level of multilateral balancing in trade had they followed more liberal trade policies. But the contrast between the two groups lends support to the earlier-drawn tentative conclusion, that foreign-trade policies followed by governments are probably not the major determinant of the level of multilateral balancing. This conclusion does not, of course, take into account the effects of an entirely different economic regime, such as that of the Communist countries, on the economy's foreign trade.

It is also interesting to observe a high degree of uniformity, with respect to the level of multilateral balancing, among (non-Soviet) European economies. In all other areas (except, of course, those which consist of only one or two countries), indexes of multilateral balancing of member countries spread over a wide range (for instance, from 12.7 to 45.4 among the 11 nondollar Latin American countries, or from 21.2 to 58.1 among the 16 countries in the Overseas Sterling Area); in Continental Western Europe, on the other hand, the level of multilateral balancing is consistently low: indexes for the 15 countries in this area range only from 19.0 to 28.5. To this phenomenon we shall return soon.

It may be rewarding to inquire whether multilateral balancing tends to be particularly important in each country's trade within a monetary area to which it belongs. This is done by means of separating the index of multilateral balancing of each country into two components, or regional indexes, measuring multilateral balancing in the country's trade within and outside its monetary area. Symbolically, the index of multilateral balancing in the country's trade within the area, to be denoted by T_{ja} , is

$$(2) \quad T_{ja} = 100 \frac{\sum_{s=1}^i \left| \frac{X_{sj}}{X_{\cdot j}} - \frac{M_{sj}}{M_{\cdot j}} \right|}{\sum_{s=1}^i \left| \frac{X_{sj}}{X_{\cdot j}} + \frac{M_{sj}}{M_{\cdot j}} \right|}$$

while the index of multilateral balancing in the country's trade outside its monetary area, denoted by T_{jb} , is

$$(3) \quad T_{jb} = 100 \frac{\sum_{s=k}^n \left| \frac{X_{sj}}{X_{\cdot j}} - \frac{M_{sj}}{M_{\cdot j}} \right|}{\sum_{s=k}^n \left| \frac{X_{sj}}{X_{\cdot j}} + \frac{M_{sj}}{M_{\cdot j}} \right|}$$

where countries 1 to i are country j 's partners in the monetary bloc, while countries k to n lie outside this bloc. T_j , the over-all index of multilateral balancing in the country's trade, is, of course, the weighted average of these two regional indexes.

Table 3 summarizes the two regional indexes for 1954 and 1958, for each of the countries in three monetary areas—The Dollar Bloc, the Sterling Area, and the Continental OEEC Area—which are included in the present investigation; for shortage of space, only the (unweighted) averages for each of the areas are presented.⁸

The findings of Table 3 seem quite surprising; at least, they diverge considerably from what the present author had expected to find. It might be expected that, for each country, multilateral balancing should be more widespread in the trade within its monetary region than in its trade with nonmember countries, since common monetary arrangements facilitate and should be conducive to multilateral balancing of trade among countries. Yet it is observed that in all three regions, the extent of multilateral balancing is lower in the trade of the region's members among themselves than in their trade with the outside world. In 1954, this holds for 34 countries out of the 42 represented in Table 3, and in 1958 it is true for 38 countries. The contrast is particularly glaring when one looks at the Dollar Bloc: Here, the index of multilateral bal-

⁸ The fuller information on which the table is based may be obtained from the author.

ancing is three to four times higher in the trade with outside countries than in the trade within the Bloc. It seems, indeed, that very little multilateral balancing is carried out inside the Bloc. Instead, each of the small trading countries conducts most of its trade with the United States; this trade is highly bilateral, and the small export or import surplus that results serves to finance (or is financed by) deficits (or surpluses) not in the trade with other countries in the region, but in the trade with countries outside it.

To a much smaller extent, this is true also for the Sterling Area: it appears that multilateral balancing is considerably less significant in the trade of the Area's members among themselves than in their trade with nonmembers. Here, too, trade surpluses (deficits) with the central

TABLE 3—INDEXES OF MULTILATERAL BALANCING WITHIN AND OUTSIDE MONETARY REGIONS (Regional Averages)

Monetary Region	1954		1958	
	Within Monetary Region (T_{ia})	Outside Monetary Region (T_{ib})	Within Monetary Region (T_{ia})	Outside Monetary Region (T_{ib})
Dollar Bloc	11.8	46.6	12.6	43.5
Sterling Area	29.0	44.1	27.3	43.5
Continental OEEC Area	19.8	25.3	18.2	26.1

member of the region—the United Kingdom—serve more to offset deficits (surpluses) with nonmember than with member nations. In contrast to the Dollar Bloc, though, a large amount of multilateral balancing which does not involve the region's center sometimes takes place in the Sterling Area.⁹

Even countries belonging to the OEEC—an organization one of whose main functions was specifically the encouragement of multilateral trade among its members—seem to be more bilateral in their trade among themselves than in their trade with other countries. It must be concluded, on this showing, that regionalization of trade cannot count intraregion multilateral balancing of trade as one of its central outcomes. Undoubtedly, common monetary arrangements do facilitate and lead to multilateral balancing, but they are apparently not overly important in comparison with other factors which affect the extent of multilateral trade. This phenomenon conforms, again, to the tentative conclusion arrived at earlier, namely, that policy measures—except when carried to extremes—have probably not been among the major de-

⁹ A similar impression is gained from Philip W. Bell's detailed study of the Sterling Area [1, pp. 296-313].

terminants of the degree of multilateral balancing in the trade of nations.

III. *Common Attributes of Highly Multilateral Economies*

What are the attributes of countries with a relatively high level of multilateral balancing in foreign trade? Examination of Table 1 will reveal a few characteristics that these countries commonly share:

1. Countries with highly multilateral trade are usually exporters of primary goods. Among the 25 countries at the top of the list in Table 1, only two—Japan and, to a lesser extent, Hong Kong—export mainly manufactures. In the rest, primary products constitute an overwhelming majority of exports.

2. These countries are underdeveloped—an attribute which is closely associated, of course, with the export of primary goods. Among the 25 most multilateral countries the only exception is Australia, a highly developed nation (i.e., one with a high per-capita income).

3. The highly multilateral countries are usually small in terms of size of foreign trade. Some of these countries may be regarded as medium-sized, but none could be classified among the “giants” in international trade. The proportion in world exports of the largest trading nation among the highly multilateral countries—Japan—amounted in 1954-55 to 2.6 per cent; and only four other nations in this group—Australia, India, Malaya, and Indonesia—had a proportion of one per cent or more of world exports in these years.

4. As could be gathered from our earlier remarks, none of the highly multilateral countries lies in Europe. The European countries with the highest level of multilateral balancing—Portugal and Spain—occupy, respectively, only the 27th and 28th places on the list, and their indexes of multilateral balancing are about the average for the 60 non-Soviet countries. This must be the result of the fact that European countries do not generally share the other three just-listed attributes. Those that do, besides Portugal and Spain, are only Turkey and Yugoslavia, and these two were in the period under consideration among the closest adherents to restrictive, bilateral foreign-trade policies in the non-Soviet world.

The “typical” multilateral country is thus a small, underdeveloped, primary-goods exporting (and primary-goods producing) economy. A few tentative explanations of this phenomenon may be offered.

One explanation may lie in the fact that such countries are likely to have a high degree of commodity concentration in their foreign trade, particularly in their exports.¹⁰ And, as has been suggested in a well-

¹⁰ See [3].

known League of Nations study, "... the concentration of trade ... prevents it from being bilateral; for the countries whose exports are largely concentrated on one or a few commodities are not likely to require, and do not require, the particular products of other countries in exactly the proportions in which these countries require their products. The same is true even in trade between countries with a more diversified trade; it is only less obvious."¹¹

Another reason for a relatively high level of multilateral balancing among exporters of primary goods is that, in the trade in primary goods, very often an "intermediary" appears between the country of origin of the goods and the countries of final destination; goods are sent abroad to a country in which they are slightly reprocessed, and from which they are further exported to third countries. When the intermediary—as well, of course, as the country of origin—is an underdeveloped, primary-goods exporting country, this process is liable to create a high degree of multilateral balancing in both the country of origin and the intermediary.

This procedure is probably most conspicuous in the case of oil. Unfortunately, most large exporters of oil are absent from this study—sometimes (as in Iraq) precisely because the final destination of their exports could not be ascertained. But a few countries which are included in the study may serve to illustrate this point: The territory of the Netherlands Antilles, which has by far the highest level of multilateral balancing in its foreign trade, fulfills the function of the intermediary; its imports consist mostly of Venezuelan crude oil, and it exports solely refined oil. It could hardly be expected, of course, that the bulk of the refined oil should be shipped back to Venezuela. Hence a high level of multilateral balancing in the trade of both the Netherlands Antilles and of Venezuela.¹² The territory of Trinidad and Tobago is in a position similar to that of the Netherlands Antilles, only less extreme. Another raw material which may provide an example of this procedure is rubber. Large quantities of rubber are shipped from Indonesia to Malaya, where the rubber is processed and re-exported. This helps to make both Indonesia and Malaya highly multilateral countries.

Further reflection upon this process will lead to an observation of a

¹¹ [7, p. 8]. In an earlier League of Nations study, a similar idea was expressed in the reverse form: "Certain countries with a highly specialized production and an export which is accordingly primarily dependent upon the sale of a small number of articles ... are greatly dependent upon triangular trade, as they often cannot dispense of enough of their products in certain countries to offset their payments due there on account of goods imported or the services of loans" [6, 1933, p. 69].

¹² Venezuela is excluded from the present study due to its large export surpluses. Had this factor been disregarded, Venezuela's index of multilateral balancing would have been found to be 43.7 in 1954-58.

more general nature: Highly developed countries, exporting mainly manufactures, have goods to offer to both underdeveloped economies, from which they buy foodstuffs and raw materials, and to other developed countries, from which they buy mainly manufactured goods. The trade relations of a highly developed economy with countries of both types may thus, potentially at least, be bilateral. An underdeveloped economy, on the other hand, when it happens to buy large quantities of primary goods (mainly foodstuffs, but also raw materials) from another underdeveloped country, cannot usually offer in exchange goods which the partner country demands. Trade relations of under-

TABLE 4—LARGE TRADING NATIONS AS AGENTS OF MULTILATERAL BALANCING, 1954-58
(in per cent)

Country	Proportional Contribution to Multilateral Trade in Twenty Countries (1)	Proportion in World Trade (2)
United Kingdom	12.7	10.8
United States	11.5	16.4
Japan	5.9	2.9
Germany	4.9	7.5
France	3.3	5.6
Netherlands	3.2	3.5
Belgium-Luxembourg	2.8	3.2
Canada	2.8	5.4
Italy	2.3	2.9
Total	50.4	59.2

developed countries among themselves are therefore less likely to be bilateral than either the trade of developed countries among themselves, or the trade between developed and underdeveloped economies.

Let us, finally, pose the following question: What countries fulfill the role of "agents of multilateral balancing," in the sense that it is deficits and surpluses in trade with these countries which enable others to maintain multilateral trade?

One may naturally expect the largest trading nations to be also the most important agents of multilateral balancing. In Table 4, attention is focused on the position of the large trading countries (which are defined, for this purpose, as countries whose proportion of either world exports or world imports exceeded 3 per cent in 1954-58). The table presents the share of the large countries in the multilateral trade of the 20 countries with highest level of multilateral balancing—the top third of the 60 non-Soviet countries. This is shown in column (1), which

represents the (unweighted) average proportional contribution of the (positive or negative) balances of trade with each of the large nations to the indexes of multilateral balancing of the 20 highly multilateral countries.¹³

It is not surprising to find that the United Kingdom and the United States are the most important agents of multilateral balancing. The apparent contradiction between this fact and the finding that these two nations are amongst the most bilateral in the non-Soviet world disappears when one recalls that the highly multilateral countries are usually small traders: the combined proportion of the 20 most multilateral countries in world exports and imports amounted in 1954-58 to 12.6 per cent—less than the proportion of the United States alone, and only slightly more than that of the United Kingdom. Thus, the small multilateral fraction in the trade of the United States and the United Kingdom is sufficient to “support” a high level of multilateral balancing in the trade of many small countries.

In general, however, the proportional contribution of the large countries to multilateral balancing is lower than the proportions of these countries in world trade (exports and imports), which are shown in column (2) of Table 4. This is true both for the whole group of the large countries and for each of them separately, save the United Kingdom and Japan.¹⁴ In comparison with the country's share in world trade, Japan is by far the most important agent of multilateral balancing in large trading nations: Japan's contribution to multilateral balancing in the trade of highly multilateral countries amounts to more than twice its proportion of world trade.¹⁵ Thus Japan, following the United Kingdom and the United States, is the third most important agent of multilateral

¹³ Thus, for instance, the figure shown in column (1) for the United States is

$$\sum_{j=1}^{20} \frac{\left| \frac{X_{uj}}{X_{.j}} - \frac{M_{uj}}{M_{.j}} \right|}{\sum_s \left| \frac{X_{sj}}{X_{.j}} - \frac{M_{sj}}{M_{.j}} \right|} \quad \text{20}$$

where country j is any of the 20 “highly multilateral” countries, X_{uj} and M_{uj} stand, respectively, for this country's exports to and imports from the United States, $X_{.j}$ and $M_{.j}$ for its exports to and imports from any country, s , and $X_{.j}$ and $M_{.j}$ for its total exports and imports. The figure is an average of the results derived by this formula for 1954 and 1958.

¹⁴ However, the “world totals” of exports and imports, by use of which the figures in column (2) were arrived at, exclude the trade of a few countries—mainly those belonging to the Soviet orbit—while trade with all countries was considered in constructing the indexes of multilateral balancing. A comparison of column (1) with column (2) thus involves a slight upward bias of the latter.

¹⁵ The figure for Japan in column (1) excludes, of course, the contribution of countries to the index of multilateral balancing of Japan itself, which is one of the 20 “highly multilateral” countries.

balancing. Since Japan's trade is only moderately large, this could obviously not have been possible without a high level of multilateral balancing in the trade of Japan itself.¹⁶

Among the smaller traders, India is in a position similar to Japan's. With a proportion of world trade of only 1.6 per cent, India's proportional contribution to multilateral trade in the highly multilateral economies amounts to 3.7 per cent. Outside the largest trading nations, India is thus the only important agent of multilateral balancing in world trade.

¹⁶ In general, the degree to which a country serves as an "agent of multilateral balancing" is a reflection of three factors: the size of the country's trade, the level of multilateral balancing in its own trade, and the size of trade of the country's partners to international trade. The larger the first two, and the smaller the third magnitude, the larger will the country's role as agent of multilateral balancing be. Thus, the United Kingdom is a more important "agent" than the United States, despite the latter's larger trade, partly because the United Kingdom's trade is slightly more multilateral than that of the United States, but mainly due to the fact that the United Kingdom trades with smaller countries. The size of partners to international trade is discussed in [4, pp. 314-16].

The figures in column (1) of Table 4 also reflect, of course, some element of chance, since they are based on trade with the 20 "highly multilateral" countries alone.

A COMPARISON OF U.S. AND SOVIET INDUSTRIAL OUTPUT

By ALEXANDER TARN AND ROBERT W. CAMPBELL*

In any effort to gauge the relative economic strength of the United States and the Soviet Union, a comparison of industrial output is of central importance. Industry is the supplier of those outputs that are of greatest concern in the current international power struggle—it is the source of the most important inputs into the military program, investment, and foreign economic assistance.

A confusing variety of statements on the relative size of U.S. and Soviet industrial output have been published in recent years. Warren Nutter has said that Soviet industrial output was about 25 per cent of the U.S. level in 1955 [23, p. 112], while Allen Dulles of the Central Intelligence Agency asserted in 1959 that the correct figure was 40 per cent of the U.S. level [22, p. 4]. Dulles' laconic statement gives no clue as to the method of analysis underlying his assertion, although it is probably based on careful research. Nutter explains his method, but it is an extremely indirect one that prompts suspicion because it compounds two kinds of index-number ambiguities. His approach is to project the alleged relative standing in 1913 to the present by means of his indexes of growth for each country.

Another analyst has concluded that Soviet industrial output in 1956 was about 48-51 per cent of the U.S. level, depending on weighting systems and estimating procedures [13]. His method involves the comparison of a number of different outputs in physical terms, and then the aggregation of these with various kinds of weights. The total number of physical output comparisons on which this result was based was, however, rather small—51 ratios in all.

The Russians have not been content to leave the question of relative industrial size to the bourgeois economists. According to V. I. Starovskii (head of the Central Statistical Administration), his agency and several other research organizations are engaged in both methodological and empirical work on comparisons of industrial output in the two countries [11]. In the same article he reports that these calculations show that

*Tarn is an independent student of the Soviet economy and Campbell is associate professor at Indiana University. The authors wish to acknowledge the helpful suggestions of Gregory Grossman at an early stage of their research.

Soviet industrial output in 1959, whether in gross or net terms, in rubles or in dollars, was about 60 per cent of U.S. output. This insensitivity to weights, plus a statement that the ruble comparison showed a higher ratio than the dollar comparison, makes one curious about his method, which however is not elaborated. Moreover, other Soviet researchers have published results far out of line with Starovskii's 60 per cent.¹

The purpose of the present article is to present the results of a fairly detailed approach to the problem, honoring the professor's admonition to "show all work and justify your answer."²

I. *The Method*

The comparison involves a combination of two approaches. For branches of industry other than engineering (we mean by this term the sector which the Russians call "machine-building and metal-working"—*mashinostroenie i metalloobrabotka*) relative output is estimated on the basis of physical production data. The first step is to determine as many physical output relatives as possible.³ These are then aggregated by means of U.S. value-added weights. Concretely, for each class of industries of the U.S. *Census of Manufactures* (mostly at the four-digit level) physical output relatives showing USSR as per cent of U.S. are determined for the main commodity or commodities in that class. For each class, Soviet industry is then assigned a value-added figure in dollars equal to U.S. value added times the output relative. When these value-added figures in dollars are aggregated for each side and compared, the resulting ratios constitute averages of the physical output relatives, weighted by U.S. value added.

As might be expected, this approach encounters difficulties in application. There arise problems of the comparability of quality of the product in the two countries, heterogeneity of output within four-digit classes and its susceptibility to meaningful measurement in physical units, coverage of the class by the products compared, availability of production data or of useful surrogate measures for imputation, and so on. The impact of these problems varies considerably from industry to industry. Accordingly the separate industry comparisons are classified

¹ According to [10, p. 86] the output of Soviet metal-working and machine-building was about 40-44 per cent of the U.S. level in 1958. Since the source also says that the share of machinery production in total output in each country is about one-third, this is clearly inconsistent with the conclusion that total industrial production is 60 per cent of U.S. industrial production.

² Not all the detailed calculations can be presented here, but they are included in a mimeographed appendix available from the authors on request.

³ We were able to find almost 200 such ratios. The sources from which the output information is taken, and the methods of estimating the ratios are explained in the mimeographed appendix.

into three categories according to our subjective estimate of their reliability. Category I embraces the comparisons that appear to be most reliable, those in Category III the least satisfactory.

The scope of the comparison has been determined essentially by the Soviet concept of industry. Thus the mineral industries are included in addition to manufacturing. Electric power generation, however, is not included, even though it falls within the Soviet industry concept. There are undoubtedly many minor differences in the inclusion boundary as, for example, the inclusion of fisheries in the Soviet case, but their omission in the U.S. case. This choice regarding scope was dictated by a desire to make the comparison as broad as possible, but also by the fact that some Soviet data which pertain to this scope are employed in the estimation of engineering output.

The four-digit classes have also been aggregated into intermediate-size groupings, such as "food and tobacco industries," and "ferrous metallurgy." In defining the borders of these groupings the Soviet industrial classification has been followed rather than the U.S. Standard Industrial Classification.⁴ The reason for this decision is again that for the estimation of engineering output Soviet data conforming to these groupings are employed. In any case the Soviet industrial classification is close enough to the U.S. that the groupings seem perfectly familiar, and are relevant to a number of questions to be asked further on.

The comparison is between Soviet output in 1955 and U.S. output in 1954. The availability of the information of the *Census of Manufactures*, and *Census of Mineral Industries* for 1954 determined the choice of year for the United States. The choice of 1955 for the USSR is based on similar expedencies—of the years in the general neighborhood of the U.S. side of the comparison, 1955 is the one for which the most abundant data on Soviet industrial output has been released. This difference in the years being compared would be of little importance except for the fact that 1954 was a recession year in the United States, but account will be taken of this fact.

For engineering industry, an approach based on comparison of output of individual commodities is not feasible, because of the heterogeneity of the output of this branch, and because of the lack of production information on many items, particularly military items. Therefore several other approaches have been employed to arrive at a range of plausible magnitudes for value added in Soviet engineering industry. The one we consider most reliable involves comparison of motive power in U.S. and Soviet industry. First, the relationship of value added to motive power is compared for the two countries in all those industry

⁴A fairly recent description of the Soviet industrial classification scheme is given in [12, pp. 267-75].

groups for which the first method has given a relative output ratio. As might be expected, in the more modern branches, and those with relatively high priorities in Soviet planning (petroleum, ferrous metals, and chemicals, for example) the ratio of motive power to value added is not far different from the ratios found in the United States. We assume that the same kind of technological policy has been followed in the engineering industry, and therefore feel justified in estimating value added in Soviet engineering industry by analogy with the ratio of value added to motive power in U.S. engineering industry.

Essentially the same use can be made of labor productivity. For each industry group value added per worker is compared as between U.S. and Soviet industry, and Soviet value added in engineering industry is estimated by analogy with relative labor productivity in those branches which would seem to be most like engineering as regards modernity, capital supply and technological history. Still other guides are the relative size of the machine tool stock in the two countries, and the size of the engineering industry relative to the rest of industry as shown by Soviet industrial statistics. All these approaches are only oblique methods, of course, but their reasonableness is supported by the fact that they indicate a fairly narrow range for the size of Soviet engineering output relative to U.S. engineering output.

II. *The Results*

A. *Nonengineering Industries*

A summary of our results by industry group and by reliability category is given in Table 1. More detailed ratios for four-digit classes are shown in an Appendix. As the table shows, the ratio of Soviet to U.S. output for nonengineering industries is about 44 per cent. There is, however, great variation in the ratio from industry group to industry group, with the ratios for groups ranging from 17.9 per cent for printing and publishing to 83.4 per cent for construction materials. For four-digit classes the variation is still greater (see Appendix). These differences are more or less what one would expect; the Russians are closest to the U.S. level of output in producers' goods industries, especially in those branches connected with the provision of investment goods. Among the producers' goods industries, they are farthest behind in fuel. The relatively low standing in this industry is explained by the fact that in the United States this is to a considerable extent a consumer goods industry producing fuel for automobiles. If petroleum is eliminated from the comparison, the production ratio for fuel rises to 54.6 per cent instead of the 31.4 per cent shown in Table 1 for the fuel industry as a whole.

The relatively low standing of another industry, chemicals, is also no surprise. The Russians themselves have emphasized that they have been very backward in developing this branch.

Of the two industries producing consumer goods the production ratio

TABLE 1—VALUE ADDED IN U. S. AND SOVIET NONENGINEERING INDUSTRIES, BY INDUSTRY GROUP
(millions of dollars)

Industry Group	USSR				U.S.	Ratio of Soviet to U.S. Total (per cent)
	Category I	Category II	Category III	Total	Total	
Food industry	7,175	1,201	68	8,444	15,739	53.6
Light industry	2,507	866	303	3,676	11,683	31.5
Lumber, woodworking, paper	2,084	2,220	—	4,304	9,770	44.0
Publishing and printing	1,124	—	—	1,124	6,266	17.9
Chemical and rubber-asbestos	730	1,452	1,571	3,753	10,685	35.0
Mineral construction mat.	1,877	1,326	376	3,579	4,293	83.4
Ferrous metals	5,297	516	589	6,402	8,646	74.0
Nonferrous metals	—	1,130	16	1,146	2,714	42.2
Fuel	3,352	162	34	3,548	11,298	31.4
Miscellaneous	70	—	611	681	2,860	23.8
Total	24,216	8,873	3,568	36,657	83,954	43.7

is higher for food than for light industry. The very low ratio for light industry is much influenced by the extreme underdevelopment of the apparel branch in the USSR. Without apparel, the production ratio for light industry would be 46.0 per cent. The difference between these two branches reflects, of course, the fact that food is more of a necessity than clothing. Within the food group the standing is quite heterogeneous. These are a number of commodities produced in larger quantities in the USSR than in the United States—grain mill products, fish, bread, wine and brandy, distilled liquor, and others. But there are a number of industries where Soviet output is less than 10 per cent of ours.

Another feature of the comparison is the nature of the results as between categories of reliability. The Soviet-U.S. production ratio is 53.0 per cent for the industries in Category I, 35.7 per cent for Category II, and only 26.6 per cent for Category III. This is what one might expect on the basis of the following considerations. The items of Category I are basic standard items produced on a large scale. They are the ones which the Russians consider most important, and therefore those for

which they keep most careful statistical records. Since outputs in these industries are relatively high, the Russians do not hesitate to release information concerning them. Items in Categories II and III are more likely to be luxury items, or "modern" items, the production of which the Russians have not yet introduced or mastered. Hence they publish less information, both because these are less vital commodities from their point of view, and because they prefer to publicize those areas where their comparative performance is best. Yet there are a great many items in Category III, the output of which we have treated as negligible. If information were found on the output of these, it might turn out that they are not so negligible as our estimating methods have made them, and the total ratio for all industry might rise appreciably.

Of our total of \$36,657 million for value added in Soviet nonengineering industries, some 66 per cent is accounted for by Category I, covering output for which we consider the available information and the resulting comparison most reliable. Another 24 per cent is accounted for by industries in Category II, and only 10 per cent by those in Category III. Thus even under the extreme assumption that the Russians really had no output of goods in Category III, the over-all ratio would still be 39.4 per cent.

B. Engineering Industry

The data available on physical output for engineering industry, though quite extensive, cover only a small part of the output of this industry. On the basis of several kinds of indirect evidence, it is estimated that the output of Soviet engineering industry would be a little less than \$30 billion of value added with a possible error of \$2 or \$3 billion in either direction. Value added in U.S. engineering industry in 1954 was \$44 billion, and so a Soviet output of \$30 billion would mean a ratio of 68 per cent. The evidence for this conclusion is as follows.

1. *Labor productivity approach.* Table 2 lists value added and the number of workers employed for both the United States and the Soviet Union in the nonengineering industry groups already discussed. The resulting relative labor productivity figures seem quite plausible in the light of what is known about the relative performance of different branches of industry. There is great heterogeneity in output per worker, with the ratios ranging from about 14 per cent in fuels to 78 per cent in primary metals. The figure for primary metals, however, is probably rather too high as a result of our inability to give identical scope to the figures for primary metals in each country. In neither country are foundries a clearly separate branch of industry. It is estimated in the Census that in the United States some 70 per cent of castings are produced in establishments classified as foundries and included in the fer-

TABLE 2—VALUE AND VALUE ADDED PER WORKER IN U.S. AND SOVIET NONENGINEERING INDUSTRIES, BY INDUSTRY GROUP

Industry Group	Production Workers (thousands)		Value Added (million dollars)		Value Added per Worker (dollars)		Soviet-U.S. Ratio
	U.S.	USSR	U.S.	USSR	U.S.	USSR	
Food industry	1,270	1,500	15,739	8,444	12,392	5,629	45.4
Light industry	2,369	2,822	11,683	3,676	4,931	1,303	26.4
Lumber, woodworking and paper	1,309	2,440	9,770	4,304	7,463	1,764	23.6
Printing and publishing	500	133	6,266	1,124	12,532	8,451	67.4
Chemical and rubber-asbestos	725	531	10,685	3,753	14,730	7,067	48.0

Ferrous and nonferrous metals	1,108	946	11,360	7,548	10,252	7,978	77.8
Ferrous and nonferrous metals without foundries	862	946	9,544	6,027	11,071	6,371	57.5
Fuel	588	1,278	11,298	3,548	19,214	2,776	14.4
Miscellaneous	344	565	2,816	662	8,167	1,172	14.3
Engineering	4,295	5,146	44,157	—	—	—	—

The data on value added for both the U.S. and the USSR are taken from the previous tables. For the U.S. the number of workers in each industry is taken from the U.S. Censuses of Manufactures and Mineral Industries. It refers to the Census concept of "production workers." For the Soviet Union, the number of workers in each industry was derived by distributing an estimated total of *rabochie* in the several categories of Soviet industry (state industry, handicraft coops, collective farms, and enterprises of cooperative trade) according to a percentage distribution of employment of *rabochie* by branch, given in [19, p. 24]. The estimated total of 16.6 million *rabochie* consists of 14.275 million in state industry [17, p. 44], 1.6 million members of handicraft cooperatives (*idem*), 400 thousand workers in collective farm industry, and 325 thousand in industrial enterprises of consumers cooperatives. The figure for collective-farm industrial workers is simply taken as equal to the number of collective farm industrial enterprises (given in [17, p. 42]). The number in enterprises of consumer cooperatives is estimated on the assumption that output per worker in these enterprises was the same as in handicraft cooperatives, and using the relative size of output in industrial coops and enterprises of consumer coops [17, p. 42].

The Soviet concept of *rabochie* and the Census concept of "production workers" do not delimit exactly comparable groups within total employment [20, p. 100]; but for the kind of aggregative comparison employed here, this difference is probably not important. In any case we are less concerned with relative labor productivity between the two countries per se, than with using it to estimate the output of Soviet engineering industry.

rous metals industry. The rest are produced in establishments classified in other parts of industry because of their primary specialization. In the Soviet Union, on the other hand, most foundries are part of machinery enterprises [3, p. 218],⁵ though the Soviet industrial classification lists do show cast-iron pipe and fittings as part of the ferrous metals

⁵ According to [2, p. 110], in 1955, 65-70 per cent of all castings were produced in machinery plants.

industry [12, p. 268]. If foundries are completely removed from the U.S. side of the comparison, but only foundry output is excluded from the Soviet side (on the assumption that the employment figure already excludes foundry workers), the relative labor productivity ratio drops to 57.5 per cent. Since there are some foundry workers included in the Soviet ferrous metal employment figure, the true ratio would be somewhat higher, perhaps as much as 60 per cent.

The important question is which of these industries is likely to be most similar to engineering industry in its relative labor productivity. If the industry groups which represent mostly production of primary raw materials are eliminated (fuel, construction materials and lumber and paper) as both inefficient in the USSR and technically dissimilar to engineering, a range of USSR-U.S. labor productivity ratios from 26 per cent for light industry to 67.4 per cent for printing and publishing is obtained. (The figure of 77.8 per cent for ferrous metals is ignored because of the considerations mentioned above.) It seems likely that relative labor productivity in Soviet engineering industry is probably somewhere within this range.

There is reason to believe that the high ratio in printing and publishing is largely caused by the relatively low labor productivity in this industry in the United States, which has a large proportion of small establishments engaged in commercial printing. Moreover, even if printing and publishing were very efficient in the USSR, this condition is not likely to apply to a much larger and more diversified engineering industry. Thus it will probably be fairly safe to eliminate the labor productivity ratio for printing and publishing as a useable index of labor productivity in Soviet engineering.

At the other extreme it is quite unlikely that labor productivity in Soviet engineering is in the same class with that in light industry or even with that in the food industry, which have been given comparatively little attention in the USSR, and in which labor productivity has grown much more slowly than in producers' goods industries, such as chemicals, primary metals, and engineering industry.

Therefore, it is probably justifiable to use the productivity range of the industries producing mainly the means and materials of production, which is between 48 per cent for the chemicals and rubber-asbestos industry and about 60 per cent for primary metals, as more likely to represent the range of labor productivity to be expected for engineering industry. In absolute terms the range for Soviet engineering output is then between \$26 and \$31 billion. We hesitate to draw more precise conclusions from this method except to say that it is likely that labor productivity in engineering industry is closer to that in primary metals than to that in chemicals and rubber. This inference is based on the

fact that until recently the chemical industry has been a relatively low-priority industry and was probably relatively backward in 1955 compared to primary metals, and probably also to engineering production.

2. *Motive power approach.* In modern industry an overwhelming proportion of work is done by means of mechanical and electrical power installations, and power capacity of industrial equipment is thus a good indicator of industrial capacity. The Russian statistics on power capacity show prime movers separately for those used to drive generators and those not used to drive generators, the capacity of electric motors, and capacity of other electrical installations such as electrolytic baths, electric furnaces, welding equipment, lighting and so on. The U.S. Census shows data separately for prime movers used to drive generators and prime movers not used to drive generators, and capacity of electric motors separately for those driven by purchased energy and those driven by energy generated by the establishment itself. The broadest of the concepts that can be developed from the Russian figures would probably be the best over-all indicator, i.e., the power of prime movers not used to drive generators, plus the power of all installations powered by electricity. But no combination of the U.S. figures is as broad as this, and it is therefore necessary to settle for a narrower concept—"motive power"—defined as the capacity of prime movers not used to drive generators plus the capacity of all electric motors.⁶ Table 3 compares the ratio of value added to motive power for all the industry groups for which we have data for the two countries.

Again there is a wide range of variation in the ratios. As one searches for explanations for these variations it becomes clear that the relationship of output to power capacity is very complicated. There are problems of the scope of power equipment included in the statistics of each country (e.g., the inclusion or exclusion of highway-type vehicles), variation in the internal composition of an industry group between the United States and the USSR, and the degree of utilization of capacity. In Table 4 adjustments have been made for these differences in cases where they are most important. Details are given in the notes to the table.

The general effect of these adjustments is to narrow the range somewhat, but in the end there is still a disconcerting range of ratios, from more than 100 in the case of ferrous metals, to as low as 50 in the case of coal mining. Our ultimate question concerns the probable position occupied by the Soviet machinery industry on this spectrum, and an an-

⁶It is possible on the basis of indirect evidence to estimate for U.S. industries the comprehensive concept of power equipment. We have done so, but the procedure is complicated and involves several uncertainties. Since the results are not in conflict with those based on motive power alone, the calculation will not be produced or summarized here.

TABLE 3—RATES OF VALUE ADDED TO MOTIVE POWER IN U.S. AND SOVIET NONENGINEERING INDUSTRIES, BY INDUSTRY GROUP

Industry Group	United States			USSR			USSR-U.S. Ratio (per cent)
	Value Added (million \$)	Motive Power (thousand KW)	\$/KW	Value Added	Motive Power	\$/KW	
Coal mining	1,615	5,622	287.2	1,546	5,837	264.9	92.2
Petroleum and gas extraction	7,674	11,769	652.1	1,568	2,076	755.1	115.8
Petroleum refining	1,901	4,679	406.2	316	874	361.5	89.0
Ferrous metals	8,646	18,191	475.3	6,402	8,239 ^a	863.3	181.6
Food industry	15,739	6,079	2,587.1	8,444	3,194	2,644	102.1
Light industry ^b	6,536	3,503	1,865.8	3,017	2,139	1,410	75.6
Chemicals, rubber-asbestos	10,685	11,383	938.7	3,753	2,999	1,251	133.3
Lumbering, wood-working and paper	9,770	10,471	933.1	4,304	4,851	887.2	95.1
Mineral construction materials ^c	3,598	3,592	1,000.2	3,579	2,758	1,297.7	130.0
Engineering	44,157	18,049	2,446	—	11,569 ^a	—	—

Notes: The figures for USSR motive power are from [19].

^a Because something like 10 per cent of Soviet ferrous metals output is accounted for by machinery enterprises, 824 thousand KW of the power shown in [19] for machinery has been transferred to ferrous metals, i.e., enough to equal 10 per cent of the power for ferrous metals shown in this table.

^b The Census does not give figures for motive power in the apparel industry, so apparel has been omitted entirely from the U.S. side of the comparison, and from the Soviet output figure.

^c The ratio for this group has been figured for a sector without sand, gravel and crushed stone on the assumption that the Soviet figures for motive power in this industry group exclude such establishments. It is stated in [19, p. 5], that the power figures given there do not include those for subsidiary enterprises; and it seems likely that most of the enterprises in sand, gravel, and crushed stone have that status in the Soviet Union. In any case, without that interpretation the Soviet-U.S. ratio of value added to motive power seems impossibly high.

swer requires analysis of the factors explaining the divergence of the ratios. Even a first inspection of past trends, and of the heterogeneous ratios within our industries suggests that any interpretation involves the interplay of the following important considerations:

(a) The output-power ratio is probably closely related to mechanization and capital intensity; and the relatively low ratio of power capacity to output for a number of Soviet industries reflects their restricted access to capital. Such branches as food processing, light industry, wood-working and paper are low-priority industries in the Soviet scheme of things, and have not been allotted the capital that would be needed to modernize and mechanize them.

(b) On the other hand, the latitude for exercising choice of capital in-

TABLE 4—ADJUSTED RATIOS OF SOVIET TO U.S. RATIOS
OF VALUE ADDED TO MOTIVE POWER

(per cent)

Ferrous metals	101.5
Petroleum refining	75.6
Chemicals, rubber, asbestos	103.0
Light industry	95.8
Petroleum and gas extraction	60.1
Food and tobacco	92.7
Woodworking and paper	182.6
Coal mining	58.5
Mineral construction materials	130.0

Ferrous metals. The ratio has been adjusted to eliminate foundries and to correct for underutilization of capacity. (1) We earlier treated foundries as part of the ferrous metals industry in line with U.S. organization and statistical practice. In the Soviet Union, however, it appears that castings are produced mostly by machinery enterprises, and the power figure reported for the iron and steel industry therefore covers only a few foundry operations. Hence, in this table the comparison refers only to ferrous metals without foundries. (2) We take 71 per cent as the operating rate of the U.S. iron and steel industry for 1954. The AISI gives 71.6 per cent for blast furnaces and 71 per cent for steel-making.

Petroleum refining. This figure is adjusted only for the low U.S. operating rate of 85 per cent of capacity, given in *Minerals Yearbook*.

Chemicals, rubber, asbestos. This figure has been adjusted for the different importance of organic versus inorganic branches in the two countries. We have reweighted the U.S. output-power ratios in accordance with Soviet structure, so as to eliminate the difference in structure as an explanation for the difference in U.S. and Soviet output-power ratios.

Light industry. Adjustment here involved reweighting to eliminate the effect of differences in intrabranch structure.

Lumbering, woodworking and paper. This ratio is adjusted for (1) differences in structure, and (2) to eliminate logging. It seems highly unlikely that the U.S. census concept of logging camps is as comprehensive as the Soviet definition of the same activity. This is suggested by the very large motive power in Soviet logging relative to that in the United States. In any case the U.S. Census data on power does not include highway vehicles, whereas the Soviet figures apparently do. So for the comparison in this table we have narrowed the sector to eliminate logging entirely.

Petroleum and gas extraction. The Census of Mineral Industries includes highway-type vehicles in its figures for power equipment. It is not clear whether the Russian data do or do not include them, but even if they do, it seems unlikely that such vehicles would amount to so high a proportion of the total as they do in the United States (i.e., 27 per cent). Hence we have simply omitted this type of power from the U.S. side, though this may result in a Soviet to U.S. ratio of output to power that is slightly too low.

Food and tobacco. This ratio has been adjusted for differences in structure.

Coal mining. This figure has been adjusted for the low operating rate of the U.S. coal industry as given in [21, p. 730].

Mineral construction materials. The ratio for this industry has been figured for a sector without sand, gravel, and crushed stone, as explained in the notes to Table 3. The ratio for this narrower scope has also been adjusted in the present table for differences in internal structure.

tensity or power intensity probably varies from branch to branch. (We can think either of technical impossibility of substitution or, probably more realistically, of differences in the second derivatives of production functions.) In well-drilling, for instance, the bulk of the power is used

in lowering and raising the string, turning the bit and pumping the mud, and the possibilities for replacing mechanical power with labor in these processes are probably very limited (or fantastically expensive). The building materials industry, on the other hand, involves a much more heterogeneous collection of processes, including many traditional branches, such as brickmaking, which can be continued on a basis of low power intensity. Thus even if there are other processes, such as cement production, where the possibilities of substitution are less, the over-all power intensity in the industry could be kept far below U.S. practice.

(c) A glance at trends in power capacity and output reminds one that there are power-saving as well as power-using innovations. Hence the Soviet output-power ratio reflects not only the degree to which power has been substituted for human effort, but also the extent to which Soviet industries have kept up with U.S. technological change. In U.S. petroleum refining, for instance, there was before the Second World War a period when growth of power capacity lagged behind the growth of output capacity. For the Soviet case there is no comparable period, suggesting that the low output-power ratio in this industry in the Soviet Union may result from Soviet failure to adopt power-saving innovations to the same extent as in the United States.

The same explanation may also rationalize the low output-power ratio in the coal industry. The Soviet coal industry presents a paradox. Labor productivity is extremely low compared to that in the United States, a phenomenon which one might explain by the very low power per worker in Soviet coal mining. On the other hand, the output-power ratio is lower in the Soviet Union than in the United States. If one could imagine the Soviet coal mining labor force appropriately decimated, we might argue that output would stay the same, and that labor productivity would rise to U.S. levels, an outcome that would be "warranted" by a power-per-man ratio comparable to the U.S. ratio. One doubts that this easy prescription for raising Soviet labor productivity in coal mining would work. The obvious resolution of the paradox is that the large motive power possessed by Soviet coal mining must be dispersed among a large labor force in small tools and machines. In a more abstract idiom, it is embodied in production functions that are certainly labor intensive, and probably also very wasteful of power, as suggested by the low output-power ratio.

Where would machinery fall in the comparison of Soviet-U.S. output-power ratio? Would it resemble light industry or coal? Our inclination is to say it would hold an intermediate place with a ratio of, say, 90-100 per cent. The reasoning is that it is a high-priority industry which has not therefore been stinted on capital and power capacity, but at the same time its technology is relatively flexible, allowing more sub-

stitution of labor for power than, say in ferrous metals. This is on the basis of the now familiar argument that there are several distinct technologies employed in the machinery industry; some processes the Russians have mechanized highly, but others have been left technologically backward, such as materials-handling and foundries [3] [5] [6].

An obvious counterquestion is whether machinery might not be more like coal mining and petroleum in its comparative output-power ratio. It is an industry where the Russians strive for high labor productivity and modernity, and one wonders whether Soviet planners might not have flooded the machinery industry with a surfeit of inefficiently used power. We are skeptical of this argument since it finds no corroboration in the power and output trends for this industry in the two countries. Machinery output seems to have grown faster relative to power in the Soviet Union than in the United States.⁷ Hence it would be difficult to make out a case for the view that the Russians have failed to offset power-for-labor substitution by power-saving innovations to the extent we have in the United States.

In any case, the assumed ratio of 90-100 per cent, adjusted for the fact that the U.S. machinery industry worked at far less than capacity in 1954 (according to the FRB indexes output dropped by 9.7 per cent from the peaks reached in 1953) implies a value added for the Soviet machinery industry of \$28-\$31 billion.

3. *Machine tool stocks.* As a third bit of evidence, consider the relative size of the machine tool stocks in the two countries shown in the following tabulation [15, pp. 4-5] [18]:

	Metal-Cutting Machines	Metal-Forming Machines
United States (1953)	1,900,000	699,000
Soviet Union (March, 1955)	1,699,000	345,000

The Russians thus had almost 90 per cent as large a stock in metal-cutting machines, and about 65 per cent as large a stock in metal-forming machines. If the U.S. stock were taken as of 1954 rather than 1953, it might be slightly larger, but not appreciably; the 1958 inventory of metalworking equipment showed an actual decline in total numbers in the United States between 1953 and 1958. It seems to be generally agreed that the Soviet machines are far less productive than U.S. machines, because they have smaller motor capacity, are less specialized, the less productive types of machines are more important in the total,

⁷ Moorsteen's index of machinery output (as given in [8]) has been used here rather than the official one; and it could be argued that Moorsteen's index, because of late-year weights and omission of armaments, really understates Soviet machinery growth.

carbide cutting tools are less extensively used, and there is a smaller proportion of automatic equipment.⁸ Despite adjustments for these differences, however, the ratios of Soviet to U.S. machines are high enough to make plausible the estimate of a Soviet engineering output some 60 per cent as big as that of the United States.

4. *Ratio to all industrial output.* As a final check on the estimate for engineering output our calculation of its size relative to all industrial output can be compared with Soviet statements on industrial structure. According to our results, Soviet engineering constitutes from 43.3 to 45.8 per cent of value added in all industry (depending on whether \$31 or \$28 billion is taken as value added in engineering). The share of engineering in value added in the ruble price system can be esti-

TABLE 5—STRUCTURE OF COST AND VALUE OF OUTPUT IN SOVIET
ENGINEERING INDUSTRY AND ALL INDUSTRY, 1955

(per cent)

	Cost Structure		Structure of Value Added	
	Machinery	All Industry	Machinery	All Industry
Materials	54.3	66.1	49.2	61.1
Fuel and energy	4.7	6.2	4.3	5.7
Amortization	4.1	3.4	3.7	3.1
Wages and social insurance deductions	33.2	21.2	30.0	19.6
Other	3.7	3.1	3.4	2.9
Profit	—	—	9.6	7.6
Total	100	100	100	100

mated as about 30 per cent of value added in all Soviet industry. This conclusion is derived from Soviet statements on the cost structures for the engineering industry and for all industry, and on the size of the wage bill in engineering industry relative to the wage bill in all industry. According to [19, p. 29] the cost structures were as shown in the first two columns of Table 5. A statement in [14, p. 18] that profit amounted to 10.5 per cent of cost in engineering industry and 8.2 per cent in all industry permits these to be converted into the structures for gross value of output shown in the last two columns. It can be estimated that the wage bill in engineering industry constituted 33.5 per cent of the wage bill in all industry [19, p. 24] [16, p. 50] [1, p. 187]. Ignoring the slight differential in social insurance rates for different industries this information taken together yields the conclusion that gross value of output of the engineering industry was 21.9

⁸ See, for instance, [4]. Granick also suggests that the Soviet definition of machine tools may be slightly broader in scope, and it is stated in the *American Machinist* inventory that the U.S. totals may slightly understate the true stock.

per cent of that in all industry. Defining value added as gross value less the cost of materials, fuel and energy, we compute value added engineering industry as 31 per cent of that in all industry.⁹

Now just such a divergence between the ruble and the dollar relationship is to be expected because of the index number effect. Machinery is much cheaper in price (and in value added) relative to other goods in the ruble price system than in the U.S. price system. The divergence in the two price structures required to make engineering output constitute 45 per cent of total value added in dollars versus 30 per cent of total value added in rubles would be U.S. value-added prices for engineering output about twice as high relative to value-added prices for everything else as in the Soviet Union.¹⁰ This relationship is more or less in line with what is known about ruble-dollar gross price ratios,¹¹ although in terms of value added the relative cheapness of machinery might well be somewhat less because of the relative cheapness of intermediate products and (perhaps) their relatively efficient utilization in machinery production compared to the situation elsewhere in the economy. This is a very indirect approach, but at least it does not imply that \$28-31 billion for Soviet machinery output is an exaggeration.

The results of the calculations so far are summarized below, indicating a Soviet output equal to 50.5-52.8 per cent of U.S. output.

	U.S. (billion dollars)	USSR
Nonengineering industries	84.0	36.7
Engineering industry	44.2	28-31
Total	128.1	64.7-67.7

⁹ We offer this as an approximation, aware that it involves some dangerous assumptions. In particular we doubt that all these relationships are drawn from a single consistent set of data. For example, the ratio of workers in engineering industry to workers in all industry is based on "industry-section" labor statistics, but it is not clear that the cost structures or the profit figures are drawn from a universe with the same outside dimensions or same internal classification. Nevertheless the figure of 30 per cent is probably a close enough approximation for our purposes here.

¹⁰ How much would the present ratio of Soviet value-added prices for engineering output to value-added prices for all other output have to change to make Soviet engineering output constitute 45 per cent of all value added rather than the 30 per cent it constitutes in the actual ruble value-added price structure? Using x to denote the factor by which Soviet value-added prices for machinery would have to be adjusted to achieve this result, we can write

$$\frac{.30x}{.30x + .70} = .45$$

$$x = 1.9$$

¹¹ Ruble-dollar price ratios for 1950 are given in [8]. It seems unlikely that the overall structure would have changed much by 1955.

These results should, however, be adjusted to the same year. The problem is not so much the slight hiatus in time as the fact that 1954 was a recession year in the United States, and so a misleading one for comparison. According to the FRB index, industrial output rose by 11.5 per cent between 1954 and 1955. With this correction, the ratio of Soviet to U.S. output in 1955 would be 45.5-47.6 per cent.

The ratio found refers to a period already seven years past and it would be desirable to know how the relative standing has changed since. Sooner or later our approach can probably be applied to 1958 using the data of the U.S. Censuses for that year. At the moment, however, there is not enough information relating to the Soviet side for 1958 to make

TABLE 6—ESTIMATED RATIO OF SOVIET TO U.S. INDUSTRIAL
OUTPUT BY SECTOR IN 1960 (per cent)^a

Food industry	66.8
Light industry	34.4
Lumber, woodworking, paper	62.4
Chemical and rubber asbestos	40.6
Mineral construction materials	155.1
Ferrous metals	109.0
Fuel	42.9
Subtotal	61.0
Engineering	98-109
Total	75.0-76.4%

^a No projection for the nonferrous metals industry or for printing and publishing was possible because of the absence of a Soviet index.

such a comparison possible. In lieu of that we have made an approximate estimate for 1960 by projecting each half of the ratio within each industry group by its respective output index (i.e., Federal Reserve Board indices for the U.S. and the Central Statistical Administration indices for Soviet output). The results of this calculation are shown in Table 6. The Russians have greatly increased their relative standing in each of the groups shown in the table and by 1960 had reached the level of about three-fourths of U.S. industrial output. This method of projection does not inspire great confidence. In contrast with the conceptual simplicity of the ratios for 1954-55 (i.e., physical ratios weighted by U.S. value-added) the ratios for 1958 are not capable of any simple interpretation. Moreover, there is always some uncertainty about the accuracy of the Soviet output indices. Nevertheless, the authors feel that the conclusions of this projection may be a fairly accurate representation of Soviet relative standing in 1960. We have been able to find enough Soviet data to apply the 1954-55 method to 1958 for two of the simpler groups (i.e., the ferrous metals and fuel industries). In both

these cases the 1958 relatives are nearly as high as those shown in Table 6 for 1960.

III. *Evaluation of the Results*

A ratio of 75 per cent for Soviet industrial output relative to U.S. industrial output seems surprisingly high, and one naturally asks to what degree this finding may reflect the idiosyncrasies of our method. There are two obvious ways in which our method may have been defective: the weighting system and the handling of quality differences.

1. *The weighting system.* Because of the great confusion that weighting problems have caused in past attempts to measure Soviet growth and relative size, it is obligatory to assess the impact of the chosen weighting system on the results we have obtained. What is the rationale of U.S. value-added weights, and how has their use affected our estimate of Soviet size compared to what we might have found with, say, Soviet value-added weights? Unfortunately, this is essentially an empirical question, and the evidence needed to answer it is simply not available. An empirical answer is not likely to be possible without access to much more detailed input-output information about the Soviet economy than is now at hand. (The Russians have constructed an input-output table for their economy for 1959 and if all the information from that study were available, our comparison could be repeated using Soviet value-added weights. Thus far, however, the only part of the flow table from that study which has been published is the northwest quadrant, i.e., the values involved in productive consumption; value of gross output or the amount of value-added components for the various sectors are not disclosed.) What is needed is either ruble-dollar ratios for value-added prices to be checked for correlation with the gross output relatives, or data permitting our gross output relatives to be converted to net output relatives and for these to be checked for correlation with ruble-dollar ratios for gross prices. All that is now available are gross output relatives and gross price relatives, and not much can be deduced from these about the possible index-number effect of using U.S. rather than Soviet value-added weights. What follows, therefore, is limited to explaining the nature of the problem.

The assumed difference between the results of a ruble comparison and a dollar comparison would involve two distinct issues: (a) a possible bias resulting in differences in technical input coefficients in the two economies; and (b) the index number problem proper.

(a) Our approach can be thought of as assuming that identical amounts of gross output in physical terms represent identical physical amounts of net output. To take coal as an example, we assume that one

ton of coal in either country stands for the net output indicated by the expression

$$1 \text{ ton of coal} - \text{coal}^{a_1} - \text{coal}^{a_2} \dots - \text{coal}^{a_n}$$

where the a 's stand for the technical coefficients showing the physical amount of each commodity, 1 through n , consumed in the production of a ton of coal. Aggregation to arrive at value added involves extending each physical flow in this expression by price. Ignoring for the moment the fact that some of the inputs come from nonindustrial branches, obviously the sum of these expressions for all n commodities, each multiplied by the level of gross output of the commodity, is identical in concept with the net physical output of industry in the sense of output left to be transferred outside industry after internal consumption within industry. All that is required to make this concept obvious is a rearrangement of the subtrahends. In this rearranged form, some aggregation is possible just in physical terms, i.e., by netting out the intra-industrial consumption, and the final step in arriving at value added is extension of net physical output by prices.

In fact the technical coefficients are probably not identical in the two countries. Suppose, for example, that all Soviet coefficients were larger than the U.S. ones. In such a situation, U.S. value-added weights can be thought of as applying U.S. gross prices to an exaggerated estimate of the net output of Soviet industry (net output in the sense of output left for transfer elsewhere in the economy after subtraction of consumption within industry). U.S. value-added weights would exaggerate Soviet output just in physical terms. Conversely the use of Soviet value-added weights would be equivalent to applying Soviet gross prices to a downward-biased estimate of U.S. net industrial output.

Obviously, some Soviet coefficients are higher than their U.S. counterparts and some are lower just because of different input mixes relative to U.S. input mixes. But apart from these differences, one could make out a good case that in general Soviet coefficients tend to be higher than U.S. coefficients. Such well-known features of Soviet industry as the high input of metal per machine, the large losses in petroleum transport and refining, the relatively low degree of utilization of timber, the high fuel input relative to power generated, and so on, give an impression that the Russians tend to be wasteful of material inputs compared to the U.S. economy.¹² Such a conclusion is easy to rationalize as simply the result of Soviet technological backwardness, not offset by substitution of labor for materials, or of capital for materials. The Russians

¹² There are some notable exceptions, as in petroleum. The U.S. value-added price for a barrel of oil represents the subtraction of much more material inputs in drilling new wells than the Russian oil industry has in fact spent on producing each barrel of oil.

clearly have a motive for labor-materials substitution, but it is difficult to think of cogent illustrations of the feasibility of this approach. It is easier to think of possibilities for using capital to reduce current material inputs, but capital is too scarce in the Soviet economy for this possibility to appeal to Soviet planners. Hence the use of U.S. value-added weights may somewhat exaggerate Soviet output relative to ours because of this overestimation of net output.

(b) Even if the technical coefficients were identical in both economies, the set of ruble-dollar ratios for value-added might still be correlated with relative gross outputs, resulting in the traditional index-number effect. But we have no way of penetrating deeply enough into the Soviet price system to know whether this would be true. We have in fact found a slight inverse correlation between the ruble-dollar ratios for gross prices and the relative gross output ratios. However, there is no reason this would have to be true of the ruble-dollar ratios for value added. Again even assuming that Soviet and U.S. coefficients (in the part of the matrix representing intra-industrial consumption) were identical, goods that are relatively cheap in the Soviet as compared to the U.S. price structure might be cheap either because of the cheapness of inputs purchased from other industrial enterprises, or because of cheap value-added components (i.e., low wage scales, high labor productivity, low profit mark-up, etc.). The same applies, *mutatis mutandis*, to expensive goods. Hence for a pair of goods A and B, we might find that, in terms of gross prices, A is more expensive compared to B in the United States than in the Soviet Union, but that this relation is reversed in terms of value-added prices. Hence there seems to be no convincing a priori reason why a comparison based on rubles would necessarily show Russian output as relatively smaller than a comparison in dollars, because of the index number problem. Nevertheless, it is not unlikely that some index number effect arises from the most obvious gross structural difference between U.S. and Soviet industry, namely, the large output and relative cheapness of engineering output in the Soviet Union. In the Soviet gross price system, machinery is relatively so cheap that it would be hard to believe that the explanation could be primarily relatively cheap material inputs or extraordinarily efficient use of them. The inputs included in value added must also be relatively cheap and productive, and it seems likely that machinery would be relatively cheap in the Soviet Union in terms of value-added prices as well as in terms of gross prices. Together with the high physical output relative for machinery, this probably gives rise to a significant index number effective as suggested earlier. The relative output ratio for all industry which we have found in dollars is probably higher than what would be found in a ruble comparison.

2. *Quality differences.* It is a commonplace that whatever one may say about quantity, the Russians are far behind the United States in the general quality of industrial output. Average octane rating is much lower for Soviet than for U.S. gasoline; the average heat content of Soviet coal is lower; the quality of construction materials is scandalous; and Soviet machinery very often compares unfavorably with U.S. models in terms of its productivity and operating costs. In the consumer goods sphere, any visitor to the Soviet Union will testify to the generally low quality of most consumer goods. The method of this paper is by nature not well adapted to allowing for these differences in quality, although a rather crude correction for quality differences has been introduced in a number of cases. We can offer no quantitative conclusions on how much weight should be given to these quality differences in assessing relative levels of industrial output; but the following comments can be made:

(a) To a considerable extent the quality problem is not independent of the production coefficients problem already discussed. If the average heat content of Soviet coal is less than in the United States this only means that more tons are required per unit of output. If Soviet window glass is thin and therefore undergoes more breakage in handling and transport, more square feet will have to be produced for each square foot finally put in place. Alternatively, low quality of one input may mean higher input requirements for some other resource—low octane ratings of fuel may mean poorer performance of engines, which means waste of the associated resource inputs.

(b) To the extent that the effect of lower quality penetrates beyond the production sphere, and in some way diminishes “welfare” derived from final output, then it is hard to imagine how this diminution might be quantified. It would be much easier to conceptualize a measurement of the quality shortfall in terms of a production possibility criterion, i.e., one could ask how much it would cost to raise Soviet quality to U.S. standards. In view of the ultimate rationale of the comparison, such would be the proper approach. We want to know when the Russians are going to catch up, and catching up quantitatively will probably require catching up qualitatively as well. Thus the present relative output benchmark ought to be corrected to take account of having to make good the quality shortfall. The real issue here is thus the parameters of quality-quantity trade-off possibilities in the Soviet economy. This is a question relevant also to the interpretation of past growth; and the various studies of the National Bureau of Economic Research have demonstrated the pressure for quality deterioration that exists in the Soviet Union (see, for instance [7, pp. 70-72]). Unfortunately, how-

ever, the kind of work required as a basis for some quantitative judgment on this question has not yet been done.

These factors might warrant discounting slightly the high ratio of Soviet to U.S. industrial output disclosed by our calculations. The possible exaggeration arising out of differences in coefficients and quality differences probably bias our results upward in some unequivocal sense; and the index number problem, growing out of the gross structural differences between the relative prices and outputs of machinery relative to that of all other industrial products in the two economies, probably results in a larger global output relative than would obtain with ruble weights. A determination of the size of the required correction must await more research and more information than the Russians now vouchsafe us on the internal structure of their industrial sector. However, it is difficult to believe that the appropriate correction could be large enough to do more than shift the Soviet relative size series back a year or two.

CONSUMPTION, SAVINGS AND WINDFALL GAINS

By MARGARET G. REID*

Friedman's theory of consumption postulates a zero correlation between consumption and transitory income. Windfall gains are presumably a pure form of transitory income. The theory holds that they tend to increase assets; and they tend to increase consumption only in so far as they increase the permanent or long-run expected income [4].

Klein and Liviatan in 1957 challenged this theory, stating [7]: "There is little direct evidence on this matter, but it seems very doubtful that we are justified in considering savings any more than various luxuries as a consumers' ultimate residual which bears the brunt of financial adjustment to changing situations."¹

Several pieces of empirical evidence bearing on windfall gains have so far been presented. Bodkin's evidence [1] [2] is of special interest because his data are a subset of those described later in this article.² He used the data for those consumer units reporting in the urban consumption survey of 1950 who had shared in the soldiers' bonus paid to veterans of the Second World War during the year of the survey.³ He found a higher marginal propensity to spend windfall gains, in the form of bonus payments, than to spend disposable income; the marginal propensities to spend were respectively .97 and .75. With consumption expenditure net of that for durable goods, the propensities were .72 and .56. Thus Bodkin's findings challenged the validity of Friedman's hypothesis.

Jones [6] used the same data to examine the marginal propensity to spend for three main budget categories, namely, food, housing and

* The author is professor of economics, University of Chicago.

¹ Klein and Liviatan present evidence that windfall gains for consumer units in the United Kingdom whose heads were retired or unoccupied were negatively related to savings [7, pp. 156-57].

² In order to simplify the conditions represented, Bodkin excluded from his set consumer units whose heads were self-employed or not employed and further restricted it to those units the age of whose head was between 21 and 45 years and to those with 2 to 4 persons.

³ Announcement was made in November 1949 of the impending distribution of the bonus, payments began in January 1950, and three-quarters of the dividends had been paid by the end of March 1950. Thus the payments were made early enough in the year so that purchases out of such receipts, even those involving considerable planning or shopping around, would have been feasible during the year of the survey.

clothing. In general, he found the marginal propensity to spend higher for windfall gains than for disposable income. His concluding remarks imply considerable doubt as to the meaning of the evidence. He states: "There remains the chance that the expenditure-windfall relationships are spurious."⁴

Krein [8] has also presented evidence on expenditure and savings out of windfall gains using data of a 1957-58 survey of Israeli families. He examined the data in various ways including the method used by Bodkin. He found the marginal propensity to consume out of windfall gains to be very low: "When durable goods are excluded from consumption, the marginal propensity to consume nondurables out of windfall income is .156." The correlation between windfall gains and disposable income of consumer units did not appear to him to account for the difference between his findings and those of Bodkin. Krein thought that the larger ratio of windfall gains to income for his than Bodkin's data might have stimulated the purchase of consumer durables or payment of debts or building up for reserves rather than consumption.

This article examines further data of the urban consumption survey of 1950. Its findings are consistent with the Friedman hypothesis and with Krein's findings, but are inconsistent with the findings of Bodkin and Jones.

I. *The Data and the Main Variables*

In the estimates that follow, windfall gains are represented by "other money receipts," that is receipts other than those classed as money income. These are defined as "inheritances and occasional large gifts of money from persons outside the family . . . and net receipts from the settlement of fire and accident policies"; they include the soldiers' bonus.⁵ Some of these receipts may have been anticipated. However, there seems no reason to suppose that the degree of unexpectedness was greater for other money receipts, *in toto*, than for the soldiers' bonus.

The observations examined are averages, for a set of places (to be defined shortly), for consumer units whose heads were wage or salary workers. Consumer units whose heads were self-employed or not employed were excluded in the hope of increasing the homogeneity of conditions, other than permanent income and windfall gains,⁶ that might affect the propensity to spend. The tendencies observed were likely to be

⁴High standard errors of the regression coefficients of windfall gains appear to have been responsible for his doubts.

⁵Rough calculations indicate that the soldier's bonus accounted for about one-half of other money receipts.

⁶The consumer units represented constitute 76.5 per cent of all those reporting. Bodkin made a similar exclusion [1] [2].

little if at all affected by transitory income randomly related to the permanent income of consumer units. Presumably, for the places represented, its mean tended to be zero.

There are 32 observations, one for each of 32 "places." These include one observation for each of the nine classes of cities, as defined by the survey, namely, large cities, suburbs and small cities of the North, South and West. In addition, there are observations for each of 23 cities or combinations of 49 cities.⁷ The combinations were made in order to increase the likelihood that the transitory income of consumer units would have a zero mean for the observations. In the case of no observation is the number of consumer units represented less than 200. The 23 cities or combinations of cities represent independent observations, and the three regional observations representing small cities are almost wholly independent.⁸ Hence, in gauging the significance of the tendencies observed one can assume that there are 26 independent observations. The consumer units of the additional 6 observations, those for large cities and suburbs, are also represented by the set of 23 cities or combinations. Such duplication serves in part as a substitute for weighting by number of consumer units reporting. In the estimates made each place has a weight of one.

Average disposable money income (Y) and other money receipts (O) are the principal explanatory variables. The variable O represents a small portion of the total funds received. For all consumer units represented O is 1.15 per cent of Y . The mean of O/Y for the 32 observations is 1.43 per cent. A considerable range exists among places, from .23 to 6.15. Among the places there is a very slight positive correlation between Y and O of .09.⁹ (See Table 2.)

In testing the effect of windfall gains three components of consumption expenditure are examined with respect to Y and O . The first two components, expenditure for furnishings and equipment and expenditure for the purchase of automobiles are suspected of being positively correlated with O . Average expenditure for such products, by place of residence of consumer units, is symbolized by C_f and C_a respectively. Average total expenditure is symbolized by C ; and the third component of consumption expenditure, which is simply the residual ($C - C_f - C_a$), is symbolized by C_o . The distribution of Y and O in the consumer account is further tested by an examination of the variation in savings,

⁷ For the most part the combinations represent cities within the same state or region. There were 49 cities altogether for which reports were secured from at least 100 consumer units (only for such places is information reported by occupation). The observations for the 23 cities or combinations of cities utilized the data for these 49 cities.

⁸ One small city is also included in the set of 23 cities or combinations of cities.

⁹ Bodkin observed a correlation between disposable income and the soldiers' bonus received of .092.

represented by two components: personal insurance and net change in assets. These are symbolized by S_1 and S_2 respectively. Thus the entire flow of receipts and disbursements in the accounts of the consumer units is examined. In interpreting some of the tendencies shown,¹⁰ it should be borne in mind that average disbursements reported in the survey of 1950 exceed average receipts; the difference amounts to 3.04 per cent of disposable money income.

All variables are expressed in arithmetic form and special attention is given to the marginal propensities to spend and to save. Estimates have been made of the correlation of the various components of consumption and of savings with Y and O . The estimating equation for C_I , for example, is:

$$(1) \quad C_I = a + bY + cO.$$

For the consumption components the partial regression coefficients b and c of such an equation represent marginal propensities to save.

II. *Other Conditions that Might Affect Tendencies Observed*

Expenditure for furnishings and equipment, expenditure for automobiles, and net change in assets have a crucial role in the test made. Hence the validity of the test seems likely to be improved if conditions other than Y and O that may affect the variation among places in C_I , C_a and S_2 can be held constant.

Owner-occupancy appears to be one such condition. Note the ratios of C_I , C_a , S_2 and O to Y shown in Table 1. Both C_I/Y and C_a/Y are somewhat higher for owner- than tenant-occupants (referred to hereafter as owners and tenants). In addition, S_2/Y is much higher for owners than tenants; and so also is O/Y . Thus it seems likely that, among places, components of consumption and savings will tend to be related to the percentage of owner-occupancy (symbolized by H). Among the 32 places, H ranges from 18 to 61 per cent. Its importance for this analysis arises from the fact that the kind of tenure seems likely to have a direct effect on C_I , C_a and S_2 , and in addition it may serve as a proxy for some conditions not otherwise represented.

The simple correlations of H with C_I , C_a and S_2 , are appreciable. (See Table 2, line 3.) It is positively correlated with both Y and O , and its correlation is higher with O than with Y . In so far as O represents the soldiers' bonus, a positive correlation of H and O is to be expected. The population expansion in various cities in 1950, to which the veterans contributed, was greater in suburbs and in cities where owner-occupancy was high than where it was low. In addition, a positive correlation between H and O would have been heightened if O had tended

¹⁰ Such as the sum of the regression coefficients of C , S_1 and S_2 .

TABLE 1—RATIOS OF EXPENDITURE FOR FURNISHINGS AND EQUIPMENT (C_f), PURCHASES OF AUTOMOBILES (C_a) AND CHANGE IN NET ASSETS (S_2), OTHER MONEY RECEIPTS (O) TO DISPOSABLE INCOME (Y), BY TENURE OF DWELLING UNIT, ALL URBAN CONSUMER UNITS, 1950^a

Tenure	Percentage of Consumer Units (1)	C_f (2)	C_a (3)	S_2/Y (4)	O/Y (5)

to be used as a down payment in the purchase of a dwelling unit; H would be in part a function of O . That this occurred seems likely: 4.4 per cent of all consumer units purchased a dwelling unit for owner-occupancy during 1950 and these units received 21 per cent of all other money receipts. O/Y , for owners by date of purchase of their dwelling

^a The estimates shown represent all urban consumer units other than those with head self-employed or not employed. All variables are in arithmetic form. See page 730 for description of the 32 urban places.

Symbols:

Y , disposable money income

O , other money receipts

H , percentage of consumer units with owner-occupancy

N , the number of owner-occupants who purchased their dwelling units in 1950 per 100 of all consumer units

A , age of head of consumer unit

C_f , expenditure for furnishings and equipment

C_a , expenditure for purchases of automobiles

C_o , total expenditure minus C_f and C_a

S_1 , outlays for personal insurance

S_2 , increase in net assets.

Source: [9, Vols. 1, 2 and 10, Table 8.]

unit, is shown in Table 1, lines 1, a and 1, b. For owners who purchased during 1950, O is 5.2 per cent of Y , and for other owners it is 1.3.

Circumstances contributing to the correlations of C_I , C_a and S_2 with H include the following:

1. Owner-occupants are more likely than tenants to own all of the furniture and equipment used. The more tenants pay for these through contract rent the lower is likely to be C_I . Hence, other conditions held constant, an increase in H seems likely to increase C_I . The difference by tenure in ownership of furnishings and equipment seems likely to be most marked for kitchen and laundry equipment. However, in this article, total expenditure for furnishings and equipment only is considered. Furthermore, the practice of landlords in providing furnishings and equipment to tenants probably differs among cities. No account is taken of this variation. Hence, H is at best a crude index of the extent to which tenure affects C_I .

2. Among places, the correlation of C_a and H is high, much higher than that of C_a and Y : namely, .714 and .249 respectively. It seems probable that H serves as a proxy for an environmental condition that affects C_a for both owners and tenants, although its effect is probably greater for owners than tenants. Owner-occupancy and reliance on the automobile for transportation both seem likely to be positively correlated with low density of land use, and the lower such density the less satisfactory is public transportation likely to be compared to the use of private automobiles.

3. The positive correlation of S_2 and H probably represents the important effect which acquisition of an equity in the dwelling unit has on the program of savings by the consumer unit.

A variety of conditions contribute to the tendencies observed for H . One not so far considered has special implications for C_I and S_2 , namely, the length of time that has elapsed since the purchase of the dwelling unit occupied. During the year when the purchase is made C_I tends to be high, and S_2 tends to be low. Net saving comes later, after the expense of acquiring and furnishing the dwelling unit. The ratios C_I/Y and S_2/Y for (1) owner-occupants who purchased their dwelling units in 1950 and (2) other owner-occupants are shown in Table 1. C_I/Y is 15.7 for those who bought during 1950 and 6.2 for those who bought earlier. In fact, C_I/Y for those owners who bought prior to 1950 is identical to C_I/Y for tenants. The effect of time of purchase on change in net assets is very striking: S_2/Y is -8 for those who bought in 1950 and 1.3 for those who bought earlier. Thus the launching of a major program of savings was associated with a marked decline in net assets as measured.

Such differences make it seem advisable, in studying the allocation of windfall gains, to hold constant the importance of owners who pur-

chased their dwelling units during 1950. The variable used is the percentage of all consumer units who purchased during 1950. This is symbolized by N , referring to those recently purchasing a dwelling unit for owner-occupancy. It has considerable positive correlation with C_I and a negative correlation with S_2 .

Age of the head of the consumer unit is another characteristic that tends to affect the proportion of the consumer dollar going to C_I and to savings. For example, C_I as a percentage of income tends to fall with increasing age of head. In addition, net increase in assets tends to be higher after the head passes 50 years of age, and is especially high where the head is 65 to 75 years of age and employed. Thus there seems reason to expect, for the set of consumer units represented in this analysis, that S_2 tends to be positively correlated with average age of the heads of consumer units. Average age of head is symbolized by A . Among the 32 places, its range is relatively small, from 40 to 44 years.¹¹

Thus there are three explanatory variables in addition to Y and O . The final estimating equation for C_I , for example, is as follows:

$$(2) \quad C_I = a + bY + cO + dH + eN + fA.$$

III. *The Findings*

Coefficients of correlation of consumption and savings with respect to income (Y), windfall gains (O) and the associated conditions are summarized in Table 3. Panel A shows coefficients with Y and O as the explanatory variables. Panel B adds H to the explanatory variables, Panel C adds N , and Panel D adds A . In general, the findings are consistent with the Friedman hypothesis. Virtually none of the windfall gains goes to the consumption of items not commonly classed as consumer capital and much of it goes to savings in the form of an increase in net assets apart from personal insurance.

With Y and O as the sole explanatory variables (Panel A), expenditure for C_I and C_a per dollar of money receipts is shown to be lower for Y than O , and the tendency to spend O is greater for C_a than for C_I . On the other hand, expenditure for other consumer products, represented by C_o , is much greater for Y than for O . In addition, there is a very marked difference between Y and O in their relation to change in net assets (S_2).

The addition of H as an explanatory variable (Panel B), modifies somewhat the tendencies shown in Panel A: (1) it reduces the marginal propensity to spend O for C_I , C_a and S_2 , and increases it for C_o , and (2) it also increases somewhat the marginal propensity to spend Y for

¹¹ The exclusion of consumer units whose heads were self-employed or not employed tends to lower the average age of head and to reduce its range among the cities.

6. A	-2.898	-7.616	-11.383	18.588	-7.482	9.219

^a See Table 2 for source of data and description of the variables. R^2 is the coefficient of determination.

C_o . Furthermore, H has a marked positive relation to C_f , C_a , and S_2 and a negative relation to C_o . These are consistent with expectations based on Table 1.

The addition of N , as an explanatory variable (Panel C), brings a further decrease in the marginal propensity to spend O for C_f and C_a . The effect is sufficient to suggest that with N held constant O has no tendency to increase expenditure for C_f . However, even with N held constant, O is positively correlated with C_a . Holding N constant tends to increase the marginal propensity to spend O for S_2 , from .59 to .72. This is not surprising since it seems likely that the greater the proportion of those purchasing dwelling units during the year of the survey

the greater the tendency for liabilities to increase more than assets, and the greater the proportion of other owner-occupants the greater the tendency for assets to increase more than liabilities.

The further addition of A as an explanatory variable affects only slightly the tendencies observed (see Panel D).

Probably the main finding is the marked tendency for O to increase S_2 . A secondary finding of considerable importance is the role of H with respect to tendencies observed for C_f , C_a , and S_2 , and hence the need, in any study of savings and expenditure for durable goods, for differentiating consumers by tenure and by year of purchase of their dwelling unit.

The interplace correlations just reviewed are consistent with the findings by Kreinin. They leave questions as to the interpretation of the tendencies observed by Bodkin and Jones.

Friedman [5] in discussing Bodkin's findings speculated on the possibility that various conditions might have resulted in windfall gains serving as proxy for permanent income. In addition, there seems some possibility that the set of consumer units receiving the soldiers' bonus were relatively homogeneous with respect to permanent income. The greater such homogeneity the greater is likely to be the importance of the random error in the income of consumer units, which presumably tends to lower the elasticity of total consumption with respect to income among consumer units.

The evidence presented here makes it seem highly probable that the receipt of the bonus in 1950, especially where the amount was large, stimulated the purchase of dwellings for owner-occupancy and hence served to launch consumer units on a savings program of considerable importance. At the same time, C/Y of such owner-occupants was relatively high. Bodkin and Jones ignored the possible influence of owner-occupancy on the flow of funds received. Furthermore, 1950, for which Bodkin's data applied, may well have been an unusual year. Purchase of a dwelling unit, especially by veterans of the Second World War was feasible with a very small down payment and the conditions of the rental market during that year created some incentive for consumers to become owner-occupants.

Kreinin also ignored the role of owner-occupancy. However, such occupancy is a much less important form of saving in Israeli than in urban areas of the United States.

IV. *Concluding Comments*

The evidence presented above, like that by Eisner [3], gives reason to suppose that interplace correlations provide a useful technique for deriving observations free from random error, and hence for studying con-

sumption and savings in relation to permanent income and conditions other than random transitory income. However, tendencies indicated by such correlations must be accepted with some reservations. Are there conditions correlated with the average income of places that affect tendencies observed? This article has demonstrated the probable effect of the nature of tenure and also of density of land use, both of which appear to be represented by the importance of owner-occupancy. There may well be other conditions, such as price. Searching for such conditions and finding variables to represent them should continue.

This article has ignored the response to windfall income of consumer units whose heads were self-employed or not employed. There seems no reason to suppose that their behavior is represented by the evidence presented. It may well be that future surveys will be adequate in scope to permit estimates for these groups to be made using interplace correlations and taking into account the variety of conditions peculiar to such consumer units.

In addition, the data examined represent an unusual economic situation. The housing market was unique in several respects and the formation of new households unusually important. The cumulation of evidence from interplace correlations for other years should permit insight into the response of consumer units to a variety of changing conditions.

INCOME AND EMPLOYMENT MULTIPLIERS, AND THE PRICE LEVEL

By PAUL DAVIDSON*

Although Keynes suggested that "the general price-level depends partly on the rate of remuneration of the factors of production which enter into marginal cost and partly on the scale of output as a whole, *i.e.* (taking equipment and technique as given) on the volume of employment" [5, p. 294], the typical Keynesian multiplier analysis has ignored the problem of changing price and wage levels as output expands or contracts.

The pedagogical simplicity of existing "real" multiplier formulations has obstructed attempts to analyze concurrent price movements. Multiplier analysis has usually been applied to the following cases: (1) the involuntary unemployment case, where prices are assumed constant and output is variable,¹ and (2) the full employment case, where output is assumed constant and prices are variable. Hence in (1) changes in money income can be directly related to changes in real income, while in (2) changes in money income are directly related to changes in the price level.

Although the usual multiplier models have given valuable insight into income generation and contraction processes, they have not been helpful for policy purposes, for they are unable to deal with simultaneously occurring economic events, *e.g.*, price movements before full employment, changes in employment levels, money-income determination, and distributive effects of expansionary and contractionary forces [10, pp. 177-78]. For example, the typical Keynesian multiplier model is incapable of explaining the continuous rise in the Consumer Price Index since the bottom of the 1958 recession despite the persistent presence of high rates of unemployment and excess capacity.

*The author is assistant professor of economics at the University of Pennsylvania. He is indebted to S. Weintraub, E. O. Edwards, L. R. Klein, A. Lerner, and E. Smolensky for helpful comments on earlier drafts of this paper, to I. B. Kravis for making available some unpublished empirical estimates, and to C. L. Leven for checking the mathematical analysis.

¹The typical involuntary unemployment multiplier system, although designated a Keynesian model, is incompatible with Keynes' *General Theory* since he there indicated that any changes in effective demand at less than full employment will affect prices as well as output and employment [5, pp. 284-86].

The purpose of this paper is to develop simple multiplier formulations which (a) are compatible with the conceptual framework of *The General Theory*² and the modern theory of the firm, and (b) are useful for policy purposes in that they permit the analysis of the effects of changes in aggregate demand on price and wage levels, employment and output levels, and money-income determination and its distribution.

Our analysis will emphasize (1) the heterogeneity of economic interests among members of the same economic group (e.g., employed vs. unemployed workers, rentier vs. entrepreneur capitalists) on such economic policy issues as inflation and/or changes in the level of employment [11, pp. 278-79] [13, pp. 58-59]; (2) the asymmetry of price-level changes and the employment multiplier in an expansion as compared to a contraction; and (3) the effect of changes in the distribution of income on expansions and contractions.

In the appendix some crude statistical estimates of the magnitude of the multipliers developed in this paper are presented.

I. *The First Model: Money-Wage Rate Constant*

The analysis will be based on the concept of an aggregate supply function as developed from its Keynesian origin [5, pp. 25, 29] by Weintraub. Given the level of factor prices, an aggregate supply function relating employment (N) to expected money proceeds (Z) can be derived "in the sense that each expected-proceeds level generates a particular amount of employment." Each proceeds quantity (i.e., expected total revenue) is obtained from individual industry supply curves by multiplying the supply prices by the associated output and summing over all industries. These sums are related to the volume of employment required for the particular output quantities via production functions [13, pp. 25-27].

The following symbols will be used in this presentation:

A —average physical product of labor

b —marginal (= average) propensity to consume of wage-earners

C_r^f —rentiers' real consumption

C_r^r —real consumption out of the gross profit residual

C_r^w —wage-earners' real consumption

²The extent to which the Keynesian framework has been obscured is most obvious in the modern theory of international adjustments. Machlup, for example, in his comprehensive study of foreign-trade multipliers assumes infinitely elastic supply curves because he is "not equipped" to deal with changing price and distributional effects. He defends his stable price assumption on the grounds that it rules out a great many complications and "there is little that a general theory can do about this mass of 'possibilities'" [9, pp. 204 n., 205]. Nevertheless, it is just these wage, price and distributional complications which are relevant for trade policies and which have attracted the attention of economists since Ricardo. (Elsewhere, I have suggested how these complications could be handled in a macroanalysis of an economy engaging in international trade [2, pp. 114-19].)

- D*—aggregate demand in money terms
D_r—aggregate demand in real terms
f—marginal (= average) propensity to consume of rentiers
F—fixed money income payments
I—money expenditures on investment
I_r—real investment
k—the reciprocal of the wage share
K—the stock of capital
M—marginal physical product of labor
MC—marginal cost
N—employment
P—price level of composite commodity
Q—output quantity of composite commodity
r—marginal (= average) propensity to consume out of the gross profit residual
w—money-wage rate
Z—aggregate supply in money terms (GNP)
Z_r—aggregate supply in real terms (= *Q*)
 α, β —production function constants

The following assumptions will facilitate the analysis: (1) we are concerned with a purely competitive closed economy with profit-maximizing entrepreneurs, (2) the money-wage rate is constant, (3) a homogeneous labor force is the only hired variable factor of production, (4) involuntary unemployment exists, (5) a composite commodity is produced by fully integrated firms using an identical technology, (6) the aggregate production function is of the Cobb-Douglas type, (7) there are no government expenditures or receipts, (8) there are three income recipient groups (wage-earners, rentiers, and profit recipients) and the real consumption of each group is a simple proportional function of the real income of that group [4, p. 95], and (9) the level of money investment expenditures is exogenously determined. This last assumption would be apropos if businessmen were to budget a given amount of money for investment and did not alter their decisions. If the period of analysis is relatively short, this supposition may approximate reality.

These assumptions impose the following conditions on the system: The aggregate production function takes the form:

$$(1) \quad Q = \beta N^{\alpha} K^{1-\alpha}$$

Consequently, at any level of factor hire, the ratio of average product to marginal product of labor (and the reciprocal of the wage share) is a constant [1, p. 194] [2, p. 110],

$$(2) \quad A/M = 1/\alpha = k$$

The price level of the composite commodity is a function of the money-wage rate and the marginal productivity of labor:

$$(3) \quad P = MC = w/M$$

Accordingly, the price level varies directly with the level of employment and consequently is different at each point on the aggregate supply function which relates employment to expected money GNP. As Weintraub has shown [13, p. 51], the shape and position of the aggregate supply curve will depend on the ratio of average to marginal product and the money-wage rate, i.e.,

$$(4) \quad Z = (A/M)wN = kwN$$

Thus, in Figure 1, Z is a linear function of N .

Money aggregate demand is equal to the sum of the money consumption expenditures of the three income groups plus money investment expenditures. Hence, an aggregate demand function in money terms can be derived given the consumption behavior of the three income groups and the investment decisions of businessmen.

Given the aggregate demand and supply functions of D_1 and Z_1 in Figure 1, then N_1 is the equilibrium level of employment and Z_A is the equilibrium level of GNP (with an implicit price level of P_1). If there is a parametric shift in the aggregate demand function to D_2 because of an autonomous rise in investment expenditures, then the new equilibrium values, *ceteris paribus*, are N_2 and Z_B , while the new price level

FIGURE 1

FIGURE 2

(P_2) is higher than the old price level (P_1) because of diminishing returns.

A. *The Multiplier*

Let us now analyze this system in greater detail. Underlying the monetary aggregate supply and demand functions will be real phenomena. The real aggregate supply curve (Z_r) relating physical output with employment is, of course, the familiar total product curve (Figure 2). Since the production function is of the Cobb-Douglas type, the total product curve rises at a continuously decreasing rate.

The real aggregate demand function can be decomposed into separate real consumption functions for each income group and real investment expenditures,

$$(5) \quad D_r = C_r^w + C_r^r + C_r^f + I_r$$

For simplicity we have assumed that the consumption of each income group is a simple proportionate function of the real income of each group. Thus, the consumption functions would be:

$$(6) \quad \text{wage-earners:} \quad C_r^w = b \frac{wN}{P}$$

$$(7) \quad \text{rentiers:} \quad C_r^f = f \frac{F}{P}$$

$$(8) \quad \text{profit recipients:} \quad C_r^r = r \left(\frac{Z - F - wN}{P} \right) = \frac{r[(k-1)wN - F]}{P}.$$

These functions have several interesting implications. Equation (7) is particularly noteworthy in that it suggests that as employment and prices rise, the real consumption of rentiers declines (although their money consumption spending remains constant). Hence rentiers are "forced" to save without accumulating either any real or monetary assets.³ Implicit in equation (8) is the assumption that a constant proportion of the real gross profit residual is distributed and that the proportion of the distributed profits spent on consumption is constant; or, if changes in the proportion of the profit residual distributed were to occur they would be offset by changes in the proportion of the distributions that are consumed [4, p. 95] [11, pp. 258-59].

Equations (6) and (8) suggest the important proposition that it is the consumption behavior of wage-earners and profit recipients which tends to give the real aggregate demand function its positive slope. On the other hand, since real investment declines as employment rises [assumption (9)], rentiers' and investment spending tends to reduce the upward slope of the real aggregate demand function (Figure 2).

In equilibrium, aggregate supply equals aggregate demand,⁴ i.e., $Z_r = D_r$. Since $Z_r = Z/P$, therefore, using equations (4) through (8), the equilibrium condition can be written as:

$$(9) \quad \frac{k w N}{P} = \frac{b w N}{P} + \frac{r[(k-1)wN - F]}{P} + \frac{fF}{P} + \frac{I}{P}$$

Multiplying through by P and expanding terms, we obtain

$$(10) \quad k w N = b w N + r(k-1)wN + (f-r)F + I$$

Solving for N :

$$(11) \quad N = \frac{1}{w[k-b-r(k-1)]} [(f-r)F + I]$$

³Weintraub has previously noted this phenomenon in analyzing his system and has some cogent comments on the often observable "forced" savings of rentiers [13, pp. 42-43, 124]. Also see Keynes' comments on "unproductive consumption" [6, pp. 124-25].

⁴A stable equilibrium exists if the excess of aggregate demand over aggregate supply decreases with increasing employment levels, i.e.,

$$(9a) \quad \frac{d(D_r - Z_r)}{dN} < 0$$

This implies that the slope of the aggregate demand function is less than the slope of the aggregate supply function.

$$\frac{dD_r}{dN} < \frac{dZ_r}{dN}$$

or

$$(10a) \quad b + r(k-1) < k$$

Rearranging terms

$$(10b) \quad b - r < k(1-r)$$

Since normally $k > 1 > b > r$, a stable equilibrium is assured.

Consequently, for a given change in I , we obtain the resultant change in N , or the employment multiplier as:

$$(12) \quad \frac{\Delta N}{\Delta I} = \frac{1}{w[k - b - r(k - 1)]}$$

The employment multiplier relates the additional employment created by an increment in money expenditures, assuming w is constant.⁵

Similarly substituting Z/kw for N in equation (11), we may solve for Z :

$$(13) \quad Z = \left[\frac{k}{k - b - r(k - 1)} \right] [(f - r)F + I]$$

Consequently, the money income (GNP) multiplier is:

$$(14) \quad \frac{\Delta Z}{\Delta I} = \frac{k}{k - b - r(k - 1)}$$

The money income multiplier relates the change in money GNP due to an exogenous increase in money expenditures.

Inequality (10a) in footnote 4 implies that the term $[k - b - r(k - 1)]$ which appears in the denominator of both multipliers, is positive, hence both of the multipliers are positive. These multipliers offer a useful contrast to the conventional "real income" multipliers which have become commonplace in the literature.⁶ Our multipliers indicate that for a given change in I , the change in GNP depends on (1) the marginal propensities of wage-earners and profit recipients and (2) the distribution of income as expressed through k . The change in employment for a given change in I , however, depends on the money-wage rate, as well as the marginal propensities (b and r) and the distribution factor (k).

⁵ Our employment multiplier differs from Kahn's concept which stressed the relationship between the increment in total employment and a given increase in employment in the investment industries [3]. Although Kahn's ratio is designated as the employment multiplier in *The General Theory*, Keynes noted that Kahn's intention was to lay down "general principles by which to estimate the actual quantitative relationship between an increment of net investment and the increment of aggregate employment which will be associated with it" [5, pp. 113-14]. Since equation (12) deals directly with this latter relationship, I've designated it as the employment multiplier.

⁶ The employment and money income multipliers may be reduced to a more familiar algebraic form by dividing their numerators and denominators by k , i.e.,

$$\frac{\Delta N}{\Delta I} = \frac{1/k}{w/k[k - b - r(k - 1)]} = \frac{1}{kw\{1 - [b(1/k) + r(1 - 1/k)]\}}$$

and

$$\frac{\Delta Z}{\Delta I} = \frac{1}{1 - [b(1/k) + r(1 - 1/k)]}$$

where $[b(1/k) + r(1 - 1/k)]$ is simply a weighted average of the marginal propensities to consume of the different economic classes which share in the increments of income.

As might be expected, the magnitude of the multipliers varies directly with the marginal propensities to consume, i.e., the greater the additional real consumption out of a given increment in real income for wage-earners and/or profit recipients, the greater the multiplier effects. Moreover, the magnitude of the multipliers varies inversely with changes in the magnitude of k , the income distribution factor. For example, should k increase, the shift in relative income away from the usually higher marginal-spending wage-earners and towards the usually higher marginal-saving profit recipients would reduce aggregate spending repercussions.

Fixed-income recipients do not appear to affect the magnitude of the multipliers. This result is not as surprising as it might at first seem since, as we have already noted, the assumption of a simple proportionate real consumption function for rentiers implies constant money expenditures by rentiers at any level of employment and prices. To the extent that rentiers consist primarily of pensioners, widows and orphans who are already spending almost all of their income to subsist, they are unable significantly to increase their money expenditures out of their current money income when employment and prices rise. Furthermore, for small changes in prices, the moral tradition against living off one's capital may be sufficiently strong to prevent these rentiers from using previous savings for consumption. Hence the money expenditures of "income poor" rentiers may be constant as their real consumption declines with rising prices. These rentiers will have a vested interest in preventing any increase in output associated with rising prices [5, p. 328].

On the other hand, wealthy individuals who receive rentier income actually receive most of their income in forms conceptually similar to wages and/or profit distributions.⁷ Hence the consumption pattern of these "income rich" quasi-rentiers may be subsumed under functions (6) and/or (8).

B. *The Price Variable*

The price of the composite commodity is given by equation (3); its differential is:

$$(15) \quad PdM + MdP = dw$$

⁷For example, in 1948, the top 5 per cent of the personal income recipients received 26 per cent of all the interest payments in the United States. Nevertheless, 44 per cent of their total income was derived from employee compensation, while 52 per cent was derived from income which is conceptually similar to profit income (34 per cent entrepreneurial income, 15 per cent dividends, and 3 per cent rental income). Fixed income payments (interest) was only 4 per cent of the total income received by this group [8, pp. 570-71, 676] [12].

If w is assumed constant, then

$$(16) \quad \frac{dP}{P} = - \frac{dM}{M}$$

or, in words, proportionate changes in the price level are inversely related to proportionate change in the marginal product of labor. Since the production function is $Q = \beta N^\alpha K^{1-\alpha}$, the proportionate change (neglecting signs) in M is equal to $(\alpha-1)$ times the proportionate change in N .⁸ Since $\Delta N/N$ can be obtained from equations (11) and (12), the proportionate change in price can be computed via

$$(17) \quad \frac{\Delta P}{P} = - \frac{\Delta M}{M} = - (\alpha - 1) \frac{\Delta N}{N}$$

Thus, for example, if $\alpha = 1/2$, a 2 per cent increase in employment will lead to a 1 per cent increase in price.

An important implication of equation (17) is that increasing employment levels are a mixed blessing to employees as a group. Since prices rise while the money-wage rate is constant, the real wage rate declines. Workers who were employed before the increase in aggregate demand find their real income declining [5, pp. 10, 17] [11, p. 265]. Increased employment, therefore, implies a real cost to the previously employed wage-earners as well as to rentiers. The newly employed, who were formerly members of a "null-income" group [13, pp. 58-60], on the other hand, experience a substantial increase in real income. Hence, the higher the initial level of employment, the fewer the wage-earners who have a vested interest in a further increase in employment and output, and the more who will bear some real cost in any further expansion. Accordingly, given a fixed money-wage rate, there is a heterogeneity of interests between employed and unemployed workers.

If dividend distributions tend to lag behind rising profit levels as the economy approaches full employment, most of the incremental profits will remain the property of the firm. Given diminishing returns and fixed money contracts, therefore, it is only (1) the fictitious legal individual—the corporation, and (2) those entrepreneurs (mainly of unincorporated enterprises) whose incomes are geared directly to profit levels who will tend to reap unmistakable benefits from an unfettered economic expansion.

⁸ From equation (2) we know that $M = \alpha \frac{Q}{N}$ or $MN = \alpha Q$. Hence

$$NdM + MdN = \alpha dQ$$

Dividing both sides of this equation by NM , it can be shown that

$$\frac{dM}{M} = (\alpha - 1) \frac{dN}{N}$$

II. *The Second Model: Money-Wage Rate Variable*

The analysis thus far has assumed a constant money-wage rate. Let us now relax this assumption and take the money-wage rate as a function of the level of employment, i.e., $w = \varphi(N)$. This money-wage function should not be interpreted as the supply function of labor. Following Keynes, our model assumes the labor supply to be a function of the real-wage rate. Nevertheless, Weintraub has demonstrated that a function relating labor offerings to money-wage rates can be derived from the demand function for labor and its implicit real wage phenomena. Whenever aggregate demand changes, *ceteris paribus*, the money demand and supply functions of labor derived by Weintraub are displaced. Our function $w = \varphi(N)$, is the locus of equilibrium points traced out by the simultaneous shifts of these two Weintraub curves [13, pp. 109-29].

A. *The Multiplier*

In this model equation (10) can be written as

$$(10') \quad kN\phi(N) = bN\phi(N) + r(k-1)N\phi(N) + (f-r)F + I$$

Solving for ΔN as before, we obtain the employment multiplier as

$$(12') \quad \frac{\Delta N}{\Delta I} = \frac{1}{[\phi(N) + N\phi'(N)][k - b - r(k-1)]}$$

A priori reasoning suggests that the money-wage rate function should have a positive minimum value and should be an increasing function of the level of employment. Hence, for illustrative purposes, we assume that $\varphi(N) = m + nN^2$. Accordingly equation (12') becomes

$$(12'') \quad \frac{\Delta N}{\Delta I} = \frac{1}{[m + 3nN^2][k - b - r(k-1)]}$$

Thus the additional employment created by a given increment in money expenditures depends on the distribution of income (k), the marginal propensities to consume out of wages and profits, and the initial level the employment. The relationship between changes in the magnitude of the employment multiplier and changes in k , b , and r are the same as in the first model. When the money-wage rate is a function of employment, however, the higher the initial N -level, the smaller the increment in employment from the multiplier repercussions, as more of the increase in money spending spills over into bidding up money wages and less into increasing real output [5, pp. 284-86].

Substituting $Z/k \phi(N)$ for N in equation (10') and solving for ΔZ , we obtain the same money-income multiplier as we did in the first

model, i.e.,

$$(14') \quad \frac{\Delta Z}{\Delta I} = \frac{k}{k - b - r(k - 1)}$$

Hence, the money-income multiplier is the same whether the money-wage rate is constant or not. What is important in determining the magnitude of the money-income multiplier is the marginal propensities of the two income groups who share in the increments of income and the relative distribution (as expressed through k) of the income increment between wage-earners and profit recipients.

B. *The Price Variable*

Dividing equation (15) by $MP = w$ and rearranging terms, we obtain

$$(16') \quad \frac{dP}{P} = \frac{dw}{w} - \frac{dM}{M}$$

i.e., the proportionate change in the price level varies directly with the proportionate change in the money-wage rate and inversely with the proportionate change in the marginal product of labor. Since the relative price increase for any given change in employment will be greater than the relative money-wage increase, therefore any autonomous increase in spending must decrease the real-wage rate while increasing the level of employment [5, pp. 10, 17].

Moreover, if some immobility or other imperfection exists in the labor market, higher starting wages may accompany increasing employment levels, while the money wage paid to previously employed workers need not change very much (a phenomenon that is often observable in white-collar occupations). Thus the average money-wage rate may be an increasing function of employment, while the previously employed workers do not share as fully in wage increases as the newly employed. In this case, the real cost of expansion borne by the previously employed workers, as well as by rentiers, will be greater than in the constant money-wage case, and the lack of zeal for increasing employment displayed by these groups is understandable.⁹

When the employment rate hovers around the 5 to 7 per cent level (as it has since the recession of 1958) most of the voters will be either rentiers, or already employed workers. Consequently the overwhelming majority of the electorate are more interested in preventing inflation than in reaching full employment. It is only the remaining unemployed (many of whom are probably disenfranchised because of race, age, residential or educational requirements), the owners of small unincorpo-

⁹ A. Lerner was helpful in developing this portion of the discussion.

rated enterprises, executives in family or closely held corporations, and the impersonal large publicly held corporations who will benefit from further increases in output and employment. It is not surprising, therefore, that the United States tolerated a 7 per cent unemployment rate throughout most of 1961, while politicians and financial writers claimed that 1961 was a year of unprecedented prosperity. The political fears of inflation overshadow the desire to mop up the remnants of unemployment once a relatively high level of employment has been obtained.

C. Ratchet Effect of the Money-Wage Rate

Finally if we assume that changes in the money-wage rate produce a ratchet effect, then once a given money-wage rate is established in the market place it is inflexible downwards. In such a situation, the employment multiplier presented in equation (12') is applicable to an increment in money expenditures, while the employment multiplier of equation (12) is the relevant one for decrements in money expenditures. Accordingly, the employment multiplier may be asymmetric, its magnitude being larger in a contraction than in an expansion.

Given a ratchet effect for the money-wage rate, equation (16') implies that the price variable may be relatively more stable during a contraction than during an expansion. Thus it is not surprising that the 1957-58 and 1960-61 recessions chiefly affected the level of employment, while the expansions beginning in 1958 and 1961 (at less than full employment) tended to affect both employment and prices.

III. *Conclusions*

Given the simplifying assumptions, the magnitudes of both the employment and money-GNP multipliers vary directly with the marginal propensities to consume of wage-earners and profit recipients, and inversely with the distribution factor (k). The money-wage rate is inversely related to the employment multiplier but does not affect the magnitude of the money-income multiplier. If the money-wage rate is an increasing function of the level of employment, then the higher the initial employment level, the weaker the multiplier repercussion will be on further increases in employment. If the money-wage rate is inflexible downwards, then the employment multiplier may be larger in a contraction than in an expansion.

The apparent complacency about recent unemployment levels in the United States is basically due to the heterogeneity of economic interests among the members of the community. As our analysis has shown, with expansions in economic activity the real income of fixed income groups and already employed workers declines, while the real income of the unemployed workers and the entrepreneurs of unincorporated and small

corporate enterprises increases. As a consequence, once the level of employment is relatively high, most members of the community fear inflation more than they desire further expansion.

APPENDIX: AN ESTIMATE OF THE INCOME AND EMPLOYMENT MULTIPLIERS

A. *The Value of the Parameters*

1. *The income distribution factor (k)*. Weintraub has presented statistical evidence that the value of k is approximately 2 for the United States economy [14].

2. *The marginal propensity to consume out of wages (b) and out of the gross profit residual (r)*. Although a number of statistical studies on the consumption-savings behavior of various economic groups have been published, none of the marginal (or average) propensity estimates have precise applicability to our theoretical concepts. Nevertheless, by using a study by Klein [7] and unpublished estimates of consumption propensities by occupational groups done by I. B. Kravis, in conjunction with the national income data of the Department of Commerce, crude estimates of b and r can be made.

Estimate of b . The consumption behavior of "all employees" can be used as an approximation for the marginal propensity to consume out of wages. Klein's and Kravis's figures tend to suggest that b would be in the .75 to .85 range, or approximately .80.

Estimate of r . The marginal consumption out of the gross profit residual is more difficult to estimate. The aforementioned studies suggest that entrepreneurs' marginal propensity to consume out of their disposable income is between $\frac{1}{2}$ and $\frac{3}{4}$. These estimates, however, are only for entrepreneurs of unincorporated enterprises, self-employed professionals, and farmers, whose total income receipts were only approximately one-third of the total gross profit residual in 1960 (see Table 1). From the other two-thirds of the gross profit residual, a little more than 10 per cent was paid out as dividends and was consequently available for consumption by profit recipients. If we assume that the marginal propensity to consume out of profit distributions is approximately the same as the marginal propensity to consume out of wages (i.e., $4/5$), then the marginal propensity to consume out of the total gross profit residual can be computed as a weighted average:

$$r = (e)(g) + (d)(h)(1 - g)$$

where e is the marginal propensity to consume out of entrepreneurial income, g is the fraction of the gross profit residual going to entrepreneurs, d is the marginal propensity to consume out of profit distribution, h is the fraction of the corporate gross profit residual that is distributed, and $(1 - g)$ is the fraction of the gross profit residual accruing to corporations. Hence,

$$r = (.50 \text{ to } .67)(.33) + (.80)(.10)(.67) = .220 \text{ to } .275$$

$$r \approx .25$$

Thus the marginal propensity to consume out of the gross profit residual (r) would approximate .25.

TABLE 1—GROSS PROFIT RESIDUAL—1960
(billions of dollars)

Business and professional income	\$36.2		
Farm income	12.0		
Rental income	<u>11.7</u>		
			\$59.9
Capital consumption allowances		\$43.1	
Indirect business taxes		45.6	
Corporate profits before taxes		<u>45.1</u>	
			133.8
Gross profit residual			<u>\$193.7</u>
Dividends—\$14.1			

Source: *Federal Reserve Bulletin*, September 1961, pp. 1102-3.

3. *The money-wage rate (w)*. The money-wage rate may be estimated by dividing total employee compensation in 1960 by total employment in that year (\$293.7 billion \div 66.7 million), i.e., $w = \$4.40$, or approximately \$4,400 per annum per employee.

4. *The parameters of the function for the money-wage rate (m , n)*. Our posited money wage function in the second model, $w = m + nN^2$ suggests an a priori relationship, where (1) there is a minimum money-wage rate level (m), and (2) as employment increases and the pools of unemployment dry up, the money-wage rate tends to rise at an increasing rate. Crude estimates for m and n can be made as follows:

Given a legal minimum wage rate of \$1.00 per hour in 1960 and a 40-hour work week, the value of m would be \$2.08 (i.e., \$2,080 per annum). If, in 1960, the level of employment was 66.7 million, while the going money-wage rate was \$4.40 and the minimum was \$2.08, then n would be .000521.

B. *The Magnitude of the Multipliers*

Using the above values for the parameters, the money-income multiplier can be estimated from equation (14) to be 2.11. If w is constant, then the employment multiplier in equation (12) is .239; if w is an increasing function of N , then the employment multiplier [equation (12'')] is .116. Thus, for example, an increment of \$1 billion in exogenous spending would increase GNP by \$2.11 billion, while employment would rise by 239 thousand, if the money-wage rate were constant, or by 116 thousand if the money-wage rate were an increasing function of employment.¹⁰

With these multiplier values, the output, income, and price effects and con-

¹⁰ After this paper was submitted, Suits published a study which corroborates our estimate. Using a 32-equation econometric model of the United States, Suits calculated that an exogenous increase in plant and equipment expenditures of \$1 billion would increase total employment by 115 thousand (as compared to our estimate of 116 thousand). See D. B. Suits, "Forecasting and Analysis with an Econometric Model," *Am. Econ. Rev.*, March 1962, 52, 128.

sequently the anti-recessionary policy implications of President Kennedy's decision, in July 1961, to increase military expenditures by \$3.5 billion (without increasing taxes) can be estimated. If wages increase with employment (as in our second model) then the additional defense expenditures will induce a 1 per cent increase in prices and a \$7.39 billion increase in money GNP. The reduction in unemployment would be only 406 thousand, as much of the increase in total spending will raise the average money-wage rate by almost .7 per cent. Consequently, unemployment (which was 5.1 million in July of 1961) would still be significantly large. On the other hand, if the money-wage rate could be constrained (by moral suasion or legislative action) then, for the same initial increase in expenditures, the employment effect would be more than twice as large; 837 thousand new jobs would be created, while the concurrent price rise would be relatively small (approximately .6 per cent).

EXECUTIVE INCOMES, SALES AND PROFITS

By JOSEPH W. MCGUIRE, JOHN S. Y. CHIU, AND ALVAR O. ELBING*

William Baumol has recently advanced the hypothesis that "the typical large corporation in the United States seeks to maximize not its profits but its total revenues which the businessman calls his sales" [2, p. 187]. Since sales maximization could very well result in bankruptcy for the firm if carried to extremes, Baumol stresses the importance of a minimum profits constraint: profits must be at least adequate to satisfy stockholders and to provide funds for growth. In building the case for his conclusions Baumol states, as a minor point in his argument, that: "Executive salaries appear to be far more closely correlated with the scale of operations of the firm than with its profitability" [1, p. 46]. It is this statement which is the principal concern of this paper. If investigations into the relationships between sales and executive incomes indicate that the correlation between these two variables is greater than between profits and executive incomes, confidence in Baumol's thesis of sales maximization might, to some small degree, be strengthened. Should the reverse be the case, his conclusions might be suspect.

Research into this subject extends back at least to the mid-1920's [8]. In more recent years two authors, Arch Patton and David Roberts have separately conducted extensive investigations into the relationships between these variables [4] [5]. The former has uncovered statistical evidence which indicates that management income is related directly to company size. He has also argued that above-average executive compensation acts as an incentive which leads to above-average profits [4, pp. 51-52]. Roberts found that the relationship between executive compensation and sales appeared to be stronger than the relationship between compensation and profits.

This article reports on a continuation of the research of Patton and Roberts. It is based upon a statistical investigation of the correlations between executive incomes, sales, and profits for 45 of the largest 100 industrial corporations in the United States, and covers the seven-year period from 1953 to 1959 inclusive.

*The authors are, respectively, professor of general business, assistant professor of statistics, University of Washington; and assistant professor of business administration, Tuck School, Dartmouth College. They gratefully acknowledge the financial assistance provided by the Agnes Anderson Fund of the University, the computer services provided by the Western Data Processing Center at the University of California, Los Angeles, and statistical assistance provided by Joann Spier.

The principal sources of statistical data on executive compensation, sales, and profits were *Fortune* and *Business Week*. The former annually publishes the dollar figures for sales and profits of the 500 largest United States corporations. *Business Week* yearly publishes data on executive incomes for approximately 100 firms. The 45 corporations selected for this sample were chosen largely on the basis of elimination. Since it was desired to study the relationships between the variables over a relatively long period, many firms had to be excluded because the figure of one or the other of the variables was not available for them in one or more of the years. However, sales, income, and profit figures for each of 45 of the largest 100 firms were available for the whole period. Although this way of selecting the data might be biased, a careful analysis of these figures does not reveal such a bias.

In the case of executive incomes, wherever stock was given to the executive we computed its market value on the exchange as of the close of business on December 31st of that year, and added this amount to the executive's other income. Another problem of some significance resulted from changes in personnel. For each enterprise we included only the income of the chief executive position as of 1953, and traced the income to this office through 1959. There were, of course, at times changes in the office-holder, and these changes were sometimes reflected in abrupt alterations in the amount of compensation paid—entirely apart from changes in sales or profits. Although this sort of change did not occur as frequently as might be expected in the corporations examined, it probably resulted in some bias in the statistics on executive incomes, and caused the correlations between income and the other variables to be less reliable than otherwise might have been the case.¹ However, since it affected the relationships between income and sales and income and profit equally, it was neutral in its effects on the relative magnitudes of the correlation figures.

In order to explore what appeared to be the most significant economic relationships between executive incomes, sales, and profits, 21 gross (simple) correlation series were computed, and from these were drawn seven sets of net correlations, tracing the relationships between the three variables over a seven-year period for all 45 firms. The arrangements of the data for the seven sets of net correlations are set forth below:

1. One set was based upon the gross relationships between sales, executive incomes, and profits for identical years from 1953 through 1959.

¹ Since sales and profits were, for the most part, increasing in the years between 1953-1959, and since executive incomes were ordinarily reduced with changes in personnel, these changes tended to lower the correlation coefficients between compensation and the other variables.

2. In another set executive compensation was lagged one year behind sales and profits.
3. Executive incomes were lagged two years behind sales and profits.
4. Sales and profits were lagged one year behind executive compensation.
5. Year-to-year changes in incomes were correlated with year-to-year changes in sales and in profits.
6. Year-to-year changes in executive incomes were lagged one year behind year-to-year changes in sales and profits.
7. Year-to-year changes in executive incomes were lagged two years behind changes in sales and profits.

Sets 2 through 7 (with the possible exception of number 4) arrange the data in a manner which is new, and enable us to explore what seem to be significant relationships between executive incomes, profits, sales, and time.

I. *Direct Relationships*

In this section we present the statistical evidence on simple or direct relationships between sales or revenues (R), executive incomes (Y), and profits (P) obtained from our sample. In each case to follow, the data on revenues, profits, and compensation for all 45 enterprises were correlated for each year 1953-59, which resulted in a set of r 's for each series of correlations.

There are three simple or gross correlations possible between executive compensation, profits, and revenues. Compensation may be correlated with either profits or revenues, or revenues and profits may be related. Suppose, for the moment, it is assumed that either the correlation between executive incomes and revenues, or between incomes and profits, is the pertinent relationship for this investigation. In order for a simple correlation to be appropriate, it must also be assumed that the intercorrelations between the extraneous variable (either profits or revenues) and the other two variables are not economically significant, and that either profit or revenue is correlated independently with compensation. Table 1 presents most of the pertinent r 's resulting from these assumptions.

The first two columns of Table 1 indicate the simple correlation coefficients for executive compensation and sales, and executive compensation and profits. Columns (3) and (4) present coefficients for the same variables, but compensation is lagged one year, and in (5) and (6) it is lagged two years. In columns (7) and (8) sales and profits are lagged one year behind compensation. The final two columns show the correlation coefficients between the changes in executive compensation and the changes in sales and profits from year to year. The so-called

1956	.58709	.55705	.60326	.63710	.58611	.61780	.58084	.57250	.11705	.03940
1957	.59215	.52141	.56873	.45625	.60526	.54753	.53061	.48951	.34173	.32816
1958	.45623	.48788	.47968	.46791	.45846	.40858	.44864	.43586	.88805	.20109
1959	.58819	.55211	.57972	.55269	.59944	.54041	—	—	.42186	.34022
Average	.6123	.5476	.5980	.5533	.5888	.5359	.5812	.5683	.4198	.1980

"averages" below the columns were found through the use of R. A. Fisher's "z" transformation, wherein:

$$(1) \quad z = \frac{1}{2} [\log_e (1 + r) - \log_e (1 - r)]$$

or, conversely

$$(2) \quad r = (e^{2z} - 1) / (e^{2z} + 1)$$

The advantage of this procedure is that the form of the distribution of z is normal, and independent of the degree of correlation. Also, the average of the z 's is not affected by extreme values, whereas the average of the r 's is so affected [3].

Note that in each set of two correlations the average gross correlation between executive compensation and sales is higher than between executive compensation and profits, and that of the 60 r 's reported in the body of Table 1, in only five instances is the correlation between income and profits higher than between income and revenues.

In order to test the significance of these correlations we used a 5 per cent level one-tail t test, wherein the computed t must be greater than 1.64 in order to be considered significant.² The formula for t is

$$t = \sqrt{\frac{\bar{r}^2(N-3)}{1-\bar{r}^2}}$$

Table 2 presents the averages for all simple correlations between either sales or profits and executive incomes, and indicates the corresponding value for t . The average correlation coefficients in Table 2 are significant, with the exception of those in column (C), rows (5) and (6). All of the variations of the relationships between sales and

² Since it was assumed that the significant variables would change in the same direction there appeared to be no reason to use a two tail test [6, pp. 200-01].

TABLE 2—VALUES OF AVERAGE CORRELATION COEFFICIENTS AND CORRESPONDING COMPUTED VALUES OF t

	(A) \bar{r}_{YR}	(B) t	(C) \bar{r}_{YP}	(D) t

^a These average coefficients are based on correlations not presented in Table 1.

executive incomes presented in Table 2, including those in which incomes are lagged by one or two years, where incomes lead revenues by one year, and where changes between the years are used concurrently, and with one and two year lags in executive incomes, prove to be significant. Except for the two cases cited, the correlations between executive incomes and profits are also significant, so that it is not possible to arrive at any definite statistical conclusion on the basis of this test.

The simple correlation analysis and t tests indicate only the statistical significance of the relationships between executive incomes, profits, and sales, and is not informative as to their economic reasonableness or importance. Furthermore, the direction of apparent causation cannot thus be ascertained. It is evident that there are six possible direct relationships between these three variables, all of which might be economically reasonable. Thus, executive incomes might be considered to be dependent upon profits or revenues, or they might be taken to cause certain profit and revenue values to result; and either profits or revenues might directly affect the other's magnitude.

Although none of the six possible direct relationships between the variables can be discarded or accepted on either economic or statistical grounds at this point, note that: (1) the \bar{r}_{YR} in each case investigated is higher than its counterpart \bar{r}_{YP} ; (2) the significance of the t 's for the correlations between sales and executive incomes is consistently higher than for the correlations between profits and executive incomes; and (3) the t 's for two of the items in the \bar{r}_{YP} column are below the acceptable level of significance.

II. Net Correlations

In order to explore further the relationships between incomes and sales or profits, and to determine the direction of apparent causation (from profits or revenues to incomes, or from incomes to revenues or

^a Because of the high $r_{YR \cdot P}$ for 1957-58, this average appears to be unusually high, and therefore may be of doubtful validity.

profits) it seemed necessary to employ statistical techniques by which the effects of one variable are removed in order to ascertain the proper relationships between the other two.³

If, for example, the purpose is to determine the relationship between sales and executive incomes, but if it must be assumed that the inter-correlation between sales and profits will significantly affect the reliability of the results obtained, unless taken into account, then the effect of profits on sales should be removed. This can be accomplished to a certain extent through net correlation, the formula for which is:

$$r_{ij \cdot k} = \frac{r_{ij} - r_{ik}r_{jk}}{\sqrt{1 - r_{ik}^2} \cdot \sqrt{1 - r_{jk}^2}}$$

where $r_{ij \cdot k}$ is the coefficient of net correlation between executive incomes and either sales or profits, with the effects of the third variable removed. The r 's on the right of the equation, of course, are the gross correlation coefficients. In Table 3 the averages of the coefficients of net correlation obtained through the use of this formula are presented, along with the related t 's

Note that the t 's for $\bar{r}_{YR \cdot P}$ are significant in every case except those in rows (4) and (7), while none of the t 's for the $\bar{r}_{YP \cdot R}$'s are significant. Thus, if the assumption that the variables involved are interrelated is proper (and it would seem to be most likely), the results of Table 3 indicate that sales and executive compensation are significantly correlated in five of the seven cases given; while profits and executive compensation are not significantly correlated. Therefore, Baumol's thesis is supported.

The two instances where the $\bar{r}_{YR \cdot P}$'s are not significant would be expected by economists. One of the cases (row 7) relates the changes in

³ This suggests the use of bunch map and confluence analysis [9, p. 149], but such a method was found to be inappropriate for this study.

sales between years 1 and 2 with the changes in executive incomes of two years later (3-4). The time lag between independent and dependent variables in this case is so extended that it would not seem probable that a high correlation would exist. Second, and more interesting, the situation in row 4 is not significant. This premise is closely allied to the Patton hypothesis that high compensation stimulates executives to work harder, and thus to produce larger sales and profits. Since all the probable permutations between executive compensation, profits, and revenues wherein compensation is taken as the independent variable have not been tested, it is not possible to state that high executive compensation is not an inducement which leads to larger profits. Nevertheless, for this one case (which appears to be the most likely case) where the executive compensation of the first year is related to sales and profits in the second, the correlation coefficients were not significant.

The Student t test in effect is informative of the distance of a given value from a hypothetical value of zero, and is presented here in terms of the standard error of \bar{r} . However, the t test is an "all or none" type of test. It indicates whether an observed value is significant or not, but it does not permit one to state that this value is more significant than another which also may be significant. In order to make comparisons between two values of \bar{r} (average correlation coefficient) we utilized a test which ended with t values based upon the differences (d) between the \bar{r} 's resulting from the net correlations of executive compensation and sales and of executive compensation and profits of identical time periods. In effect, our null hypothesis was that the expected value of the differences between the net correlation coefficients of $YP \cdot R$ and $YR \cdot P$ is zero; and the actual t values which we obtained by subtracting $YP \cdot R$ from $YR \cdot P$ would indicate whether we would accept or reject the hypothesis. The differences between the average net correlation coefficients (\bar{r} 's) for $YP \cdot R$ and $YR \cdot P$, and the corresponding t values for these differences are presented in Table 4.

In this table the t values indicate the significance of the differences between the average correlation coefficients of $YP \cdot R$ and $YR \cdot P$, or, in less technical terms, how much more significant $YR \cdot P$ is than $YP \cdot R$. Unfortunately, since even here t is an "all or none" test, we can state only that the differences between the two comparable \bar{r} 's are either significant or not significant in terms of the value of t (1.64) at the 5 per cent level. Thus, in Table 4, there exists a significant difference between the \bar{r} values of $YP \cdot R$ and $YR \cdot P$ in all cases except rows (1), (4), and (7). The latter two instances were not significant in Table 3, and the differences between the \bar{r} values, as might have been expected, were not sufficiently large to be significant. In the first instance (row 1) the net correlation coefficients for $YP \cdot R$, while not significant, were relatively

^a Because of the high $r_{YR \cdot P}$ for 1957-58, this average appears to be unusually high, and therefore may be of doubtful validity.

high, and those between $YR \cdot P$, while significant, relatively low; so that the differences between the two would not be expected to be significant.

We therefore appear justified in stating, from the results presented in Tables 3 and 4, that in most instances tested $YR \cdot P$ is significant and $YP \cdot R$ is not, and that furthermore, in most cases even the differences between $YR \cdot P$ and $YP \cdot R$ are significant. Finally, the evidence presented would seem to support the likelihood that there is a valid relationship between sales and executive incomes as Baumol assumed, but not between profits and executive incomes, although, because of the statistical problems involved, the tests employed do not completely rule out the possibility of a valid relationship between profits and executive incomes too.

If then sales and executive incomes are related, in what manner are these two variables combined most satisfactorily? First, it would appear from this sample that the line of apparent causation runs from sales to incomes rather than from incomes to sales. In other words, when the board of directors of an enterprise (or whatever person or persons make such a decision) determines executive compensation, this decision is affected significantly by current or past sales, or by realized changes in sales. Executive compensation is primarily a reward for past sales results, and is not necessarily an incentive to future sales efforts, or, if it is an incentive, it has not proved to be too satisfactory for these 45 firms for the period examined in this study.

Second, if executive compensation is most significantly related to current or past sales, which of these is the most important cause of executive incomes? We have examined six situations which might possibly apply: (1) executive compensation is a function of current sales; (2) compensation is dependent upon last year's sales; (3) it is dependent upon the sales of two years before; (4) the change in compensation between any two years is a function of the change in sales between the

same years; (5) the change in compensation between any two years (1 and 2) is dependent upon the change in sales that occurred between the preceding two years (year 0 and 1); (6) the change in compensation between years 3 and 4 is a function of the change in sales between years 1 and 2. The only one of these situations which can be eliminated as not consistently significant is (6). The correlations between the other possibilities are such that one cannot be said to be more statistically significant than the others. However, we can speculate upon these relationships.

Executive compensation in any one year is the resultant not only of current, but also of past decisions. In any one year executive compensation changes (or does not change) from a base established in the preceding year, and this compensation in turn is made up of an incremental increase or decrease (or no change) over the year before. Even when a new top executive takes over an enterprise, his basic income is in some manner related to past decisions on executive incomes in general within the firm [7]. Thus, if executive incomes are a function of sales, it is not surprising to find that these incomes are significantly related not only to current sales or changes in sales, but also to past sales levels and changes. It is likely, however, that the relationship between past sales and current compensation becomes of lesser significance as the time interval between the two increases. In fact, this may be the reason why relationship (6) is not as consistently significant as the other sales-compensation correlations.

ECONOMIC GROWTH IN THE UNITED STATES*

A Review Article

By MOSES ABRAMOVITZ

Few things have been more common in recent economics literature and in political pronouncements than expressions of dissatisfaction with the pace of U.S. economic growth, accompanied by ringing demands that we "can and must" speed the pace of our development. And, of course, few things have been less common than objective analyses of the grounds for dissatisfaction or coherent and comprehensive programs for accelerating our growth. This is the gap that Edward Denison's book attempts to fill. His work is, in fact, a notable contribution to a vexed and difficult subject. In astonishingly brief compass, Denison presents a picture of past trends in output growth and in the development of the various sources to which the growth of productive capacity can be traced, a projection of the probable future flows from these sources, and a measured evaluation of the possible steps that might be taken to make the flows still larger. Moreover, in grappling with these complicated and still largely unexplored issues, he has achieved a quite remarkable combination of technical finesse and depth with clear and almost deceptively simple exposition. The book is, therefore, a minor miracle of lucidity and persuasiveness which calls for the most serious study by economists while it engages the attention of a much wider audience.

It would perhaps be too much to say that, with the appearance of Denison's book, the whole subject of U.S. economic growth has been decisively clarified, that we now know where we have come from, where we are going, and what we can reasonably try to do about it. Unfortunately, our statistical records do not permit some issues regarding past trends to be resolved. Crucial questions regarding the sources of growth are settled in Denison's book by the author's *ex cathedra* pronouncements rather than by reference to those empirically tested production functions on which the author would prefer to rely but towards which economists are only now beginning to grope. Unavoidably built on shaky foundations, Denison's judgments about future trends and about policy issues, though models of caution and restraint, are necessarily of uncertain value. Nevertheless, Denison's book does more than any other to bring our knowledge—inadequate as it is—to bear on the amazingly wide range of issues involved. It is, at the very least, a beautifully or-

*A review of E. F. Denison, *The Sources of Economic Growth in the United States and the Alternatives Before Us*. Supplementary Paper No. 13. New York: Committee for Economic Development, 1962. Pp. 308.

dered program for research and a reasonable, indeed an indispensable, basis for discussions of policy.

While Denison's work challenges attention and comment in its sections dealing with the trend of past growth and in those which attempt projections of the future, the core of the book, as its title suggests, consists in its analysis of the "sources" of past growth and in its discussion of the various measures we might now take to make the flow from these sources more rapid in the future. It seems best, therefore, to confine this review chiefly to these two subjects.

I. *The Sources of Growth in the United States*

The growth Denison seeks to explain is growth in *capacity* to produce or, as he sometimes calls it, *potential production*. The production with which he is concerned is *measured* output, that is, the output whose value is aggregated to form the net or gross national product. The *sources* of growth are changes in those elements into which output can be immediately resolved, that is, inputs of factors of production and factor productivity, changes in the latter being further attributed to the advance of knowledge, scale effects, and gains or losses from reductions or enlargements of market restraints, lags in application of knowledge, and similar causes.

Denison's approach represents an expression of the method of analysis introduced by Jacob Schmookler [8] and by various students at the National Bureau of Economic Research and given its most complete and systematic statement in John W. Kendrick's recently published work [4].¹ The novelty and contribution of Denison's analysis is best brought out by comparison with that of Kendrick and his colleagues. In simplest form, these writers distinguished two broad categories of inputs: labor services measured in employed man-hours; and services of capital stock, including land, measured as the real net stock available after depreciation. The two categories of inputs were combined into an index of total input of resources, weighting each category by its base-period earnings. The essential meaning of the index of total factor input is that it shows how national product would have grown had earnings per unit of each input remained at its base period level with changes only in the quantities of the inputs. If these index numbers are now divided into corresponding index numbers for national product, one obtains an index of output per unit of input, sometimes called an index of productivity.

Denison did not follow Kendrick in one further step: Kendrick's labor input is a weighted aggregate built up from the man-hours utilized by 13 separate major segments of the economy and by industry groupings within 5 such segments, the weights being average hourly earnings; and his input of capital is likewise a weighted aggregate of net capital stock available in some 5 major segments and 20 manufacturing industry groups, the weights being average capital compensation (or nonlabor income) per unit. The net effect of this weighting scheme is that input increases if *either* the physical quantity of

¹F. C. Mills [7] did the first work of this kind at the Bureau followed by Fabricant [2] and the present writer [1], both of whom took advantage of Kendrick's work then in progress.

labor or capital used in any sector grows *or* if the proportion of labor or capital used in sectors with relatively high returns becomes larger. The rationale for the use of such weighted indexes of inputs is that interindustry differences in average earnings are thought to represent differences in the quantity of actual input or contribution to output associated with a nominal unit of labor or capital reflecting ultimately differences in the quality of such units (cf. Kendrick [4], p. 33). This is clearly a moot point with which Denison takes issue.

Indexes of input and productivity obtained by this procedure can be given precise significance only to the degree that several far-reaching assumptions are valid. First, units of inputs in each class distinguished must be of uniform quality and their relative rates of remuneration in the base period proportionate to their marginal productivities. Next the quality of resources in each class should remain unchanged over time and relative marginal productivities should not alter because the relative quantities of the factors vary or because shifts in the production function are not neutral.² To the extent that these conditions of constancy do not obtain, the index of "productivity" derived will reflect the effects of changes in the quality or relative quantities of factors of production. Even so the index of productivity will only represent the effect of "costless" advances in applied technology, managerial efficiency, and industrial organization ("cost"—the employment of scarce resources with alternative uses—is, after all, the touchstone of an "input") when, in addition, we can neglect the undifferentiated consequences of other factors: the so-called "unconventional inputs," such as investments or expenditures for education, health and research, the effects of economies of scale resulting from the growth of all inputs, and the effects of changes in the effectiveness of resource use associated with changing degrees of monopoly power and of other restrictions on output or the most economical use of resources. In recognition of these ambiguities, the index of productivity produced by Kendrick and his predecessors has been dubbed by some a "measure of ignorance," and it is often referred to simply as the Residual.

In its very broad lines, Denison's method is similar. Like Kendrick, he combines labor input and capital input, weighting each by its base-year earnings, to obtain an index of total factor input whose meaning is the same as that of Kendrick's. And, like Kendrick, he obtains an index of productivity by dividing an index of real national product by his index of total factor input. Denison's measures of labor and capital input, however, are differently constructed, and the Residual is broken down in an attempt to reveal its constituent elements. He substitutes a measure of the gross (that is, undepreciated) capital stock for measures of the net capital stock usually employed.³ He rejects the

² Troubles from this source were minimized by Kendrick, and by Denison as well, since each first divided the long period they studied into subperiods and constructed separate indexes of inputs for the various subperiods, weighing by the relative earnings of the input classes in each subperiod. They then chained the subperiod indexes so derived to obtain a continuous index for the entire span of years they studied.

³ Like Kendrick, Denison distinguishes several classes of capital stock, which he combines by weights based on rates of return. But Denison's classification is by type of capital, Kendrick's by industry.

procedure—of weighting man-hours in separate industries by their average hourly earnings—by which Kendrick tries to allow for the effect of shifts in the industrial composition of the labor force on the quality of labor input. Denison's procedure is more direct and, in a sense, more radical. He starts with a measure of the over-all contribution of aggregate man-hours and then adjusts it for changes in several specified elements of quality: the increased experience and better use of women; changes in the age-sex composition of the labor force; greater efficiency per man-hour associated with reductions in hours worked per week and year; and the rise in the level of education. The treatment of labor input goes a certain distance towards freeing the Residual from the impact of shifts in the quality of inputs associated with demographic changes and from unconventional inputs—in this case, expenditures for education. But Denison breaks open the Residual still more widely by making allowances for the effects of changes in various kinds of market restrictions on the movement of productivity, for economies of scale, and for the advance of knowledge.

The effect of these differences can be seen most clearly by displaying Denison's results in tabular form. Table 1, lines 1-8, shows the outcome of his analysis as it would have appeared had he stopped at the same stage as earlier writers had done. It shows the very large part of total output that remains to be explained by the Residual when the only inputs accounted for are capital⁴ and undifferentiated man-hours and when the contributions of these inputs to growth are given weights based on their base-period earnings.⁵ For comparison,

⁴ Denison's capital, as already noted, is an index of gross stocks in five categories weighted by rates of return.

⁵ It is worth a digression to notice that Denison's figures do not suggest any long-term

lines 9-11 provide figures based on Kendrick's input calculations and Denison's (that is, Department of Commerce) national income estimates. The dif-

retardation in the rate of growth of national income. The pronounced retardation in the growth of both labor and capital inputs is offset by an equally pronounced acceleration in the growth—from all causes—of output per unit of input. Kendrick's input calculations, taken in conjunction with the Denison (Commerce) income estimates, lead to the same conclusions. If one may regard the periods distinguished by Denison as suitably long and comparable, it would appear that current discussion of retardation in growth is actually concerned with the experience of a relatively few recent years, a period hardly adequate, in view of the unsteadiness of growth rates, to provide evidence of a secular drift. Kendrick's own estimates of net national product, which are based on Kuznets' work up to 1929 do, indeed, show some retardation between the period 1909-29, when the growth rate was 3.45 per cent per annum, and 1929-57, when it was 2.93. But again, this was entirely a question of retardation in the growth of labor and capital inputs, offset—but not completely—by acceleration in productivity growth.

ference between Kendrick's and Denison's estimates of the contributions of input—and the complementary difference between the contributions of the Residual—is not large. Such as it is, it derives in small part from the somewhat different procedures they use to estimate capital input. The major part of the difference, however, represents the fact that Kendrick's labor input is derived from a weighted sum of man-hours in a considerable number of industries, the weights being hourly earnings. The contribution of labor is, therefore, augmented by the shift of labor over time from industries in which average earnings were relatively low to those in which they were relatively high.

By contrast with this relatively simple set of figures stands Table 2 in which Denison summarizes his own work.⁶ Comparison of the two tables reveals a number of striking differences. Most prominent is the large reduction in the apparent importance of the increase in output per unit of input to under half its former size. Three adjustments in labor input account for the bulk of the change. Two large adjustments are made to allow for the alleged effects of shorter hours and of the rise in the level of education upon the quality of labor input per hour worked. A third, smaller, adjustment takes account of the fact that women in the labor force have come typically to represent a more experienced group employed at work which makes better use of their talents. The Residual, moreover, no longer seems just that. It has seven different parts, each with a name, the two largest of which are "economies of scale" and "advance of knowledge." Moreover, even the items in the table which have small numbers attached to them provide substantial pieces of information. They tell us that certain characteristics of the economy, which might have been deemed important for growth, in fact were not. Denison, in short, appears to have done what every economist concerned with the subject has hoped would be done, namely, broken down the Residual into its component elements. The inevitable question is whether his attempt is successful. I propose to tackle this question in brief comments on the major elements in Denison's adjustments.

Hours of Work and Labor Productivity

Denison argues with considerable plausibility that when hours of work are very long, workers' output per man-hour is lower than it might be. Presumably they cannot work either as hard, as carefully, or as cleverly as they would were their daily, weekly, and annual stints shorter. Consequently, when hours are reduced, one may suppose that some parts of the potential loss occasioned by the reduction in hours are offset by greater productivity per man-hour, and this offset ought to be counted as an increase in labor input.

To implement this position, Denison adopts a specific formula which expresses the hypothesis that the productivity offset to a given reduction in hours varies inversely with the number of hours in the working year. He places the point at which a slight reduction in hours is just offset by the rise in output per man-hour at the level prevailing in 1929 (when the level was 2592 hours

⁶ There are some very small differences in individual figures since Table 1 is drawn from Denison's Table 19 and Table 2 from his Table 32. In the latter, figures are slightly adjusted to eliminate a portion of the increase in inputs considered not to be represented in the increase in measured national product.

a year or 48.6 a week) and assumes that, at the level prevailing in 1957 (2069 hours per year or 39.8 per week), a slight change in hours was offset to the extent of 40 per cent by an opposite change in man-hour output. He interpolates between these years and extrapolates backward and forward. The result, as Table 2 indicates, is that the reduction in hours between 1909 and 1929 is treated as fully offset by an associated improvement in productivity, and that between 1929 and 1957 is treated as offset by slightly over 60 per cent. On this assumption, of course, the implications for the future are serious. Since productivity offsets are now much smaller than they were and are becoming still smaller, labor input is destined to follow the curve of man-hours more closely and future reductions in hours, to the extent that they occur, will weigh more heavily on our growth rate.

Denison, of course, is properly reserved about this calculation. He claims no more for it than that it constitutes a formula which *may* be reasonably correct. ("... its merit is that it is consistent with general pattern of expectations and is not, I think, demonstrably wrong"). It is not demonstrably wrong, but the fact remains that the theory on which Denison relies is no more than speculation and his special formula no more than a guess. Granted that there has been an historical association between shorter hours and greater intensity of work, it is plausible to argue that the underlying cause has been a stream of innovations in technology, factory organization and discipline, layout and flow of work, modes of remuneration (piece rates and bonus schemes), selection and assignment of workers and other aspects of personnel management which acted to speed the pace of work, to control its quality, and to reduce waste in the use of materials and equipment.⁷ Innovations of this character have, of course, joined with larger quantities of capital, cost-reducing technology and other forces to raise the marginal productivity schedule for labor. On their side, workers have reacted, partly through the collective processes of union organizations, by taking a portion of their potential gains in greater leisure. A priori, however, it is not at all clear that this part exceeds the portion of the gain in labor's marginal product associated with those improvements in management and technology which made for greater intensity and quality of work. Yet it is only in so far as declines in hours did pass this moving point that they could be said to have an independent effect on output per man-hour. Denison's calculations may, therefore, overstate the rise of labor input as much as the simple identification of labor input with man-hours understates it.⁸ These views are, of course, no less—but possibly also no more—speculative

⁷ In another connection Denison is led to write as follows: "It would be difficult to find technological innovations with an impact on production exceeding that of the introduction of interchangeable parts, or of the assembly line, or of time and motion study and all that has flowed from it. . . . The design of factory buildings has been radically changed to permit the easy flow of materials. . . . Improvements in work scheduling, [and] in personnel relations . . . are in this category . . ." [p. 232].

⁸ One minor point is that, though man-hours on the job itself fell, there were many years when true leisure time did not increase quite as much. Travel time tended to increase for all grades of labor, and work-connected activities outside of regular hours probably became more demanding for a larger group of salaried officials.

than Denison's. I am, therefore, led to take my stand with Denison at another point, where he writes (p. 39): "Few studies offer more promise of adding to welfare and contributing to wise decisions in a matter that may greatly affect the future growth rate than a really thorough investigation of the present relationship between hours and output."

Education.

Doubtless every economist who has looked at the large size of the Residual in earlier studies has speculated on the possibility—indeed the probability—that a large part of the explanation might be found in the rapidly soaring levels of education attained by representative members of the labor force. Denison has now attempted to measure the contribution made by education to our past growth.

His procedure begins with an estimate by Houthakker [3] (based on a $3\frac{1}{3}$ per cent Census sample of males) of the mean incomes earned before tax in 1949 by men classified in 8 groups according to age and years of school completed. This Denison reduces to a set of typical differentials by level of education for males of the same age. He treats these differentials as preliminary indications of the difference which specified amounts of schooling would make to the output of randomly chosen individuals. It is only a preliminary indication, however, because the observed differences between mean incomes for various levels of schooling are not due to differences in education alone. There are good reasons to think that differences in schooling completed are correlated with ability, energy, and motivation, also with the education and income of parents, and with parents' occupations and age of marriage. (Some of these correlates, however, may themselves be partly attributable to education—or to education of an earlier generation—for example, motivation and parents' schooling.) Denison deals with these complexities forthrightly and assumes that only 60 per cent of the observed differences are due to differences in schooling.

He next combines the adjusted differentials for 1949 with estimates of the distribution at various past dates of males, 25 and over, by years of school completed. In this way, he obtains estimates of past change in average income due to the rise in education measured in school years completed. These estimates, however, remain to be adjusted to allow for the rise in the number of school days represented by each school year, a figure which has been rising as fast as the average number of school years completed. And Denison makes the necessary adjustment by assuming that increasing the number of days spent in school per year raised a man's contribution to production as much as did an equal percentage increase in number of years spent in school.

These calculations, on their face, indicate that the contribution of the rise in levels of schooling was very high indeed. They suggest that the rise in output per man due to education was proceeding at a pace of .93 per cent per annum from 1929 to 1957 (fully 1 per cent per annum from 1940 to 1950 and .99 per cent from 1950 to 1960). Allowing for the weight of labor's share in the national income (73 per cent), the indicated contributions of education

to the growth of national product during 1929-57 would have been .68 percentage points, or 23 per cent of the growth rate of aggregate national product and 42 per cent of the growth rate in product per person employed. They indicate that the rising level of education contributed more than any other source to the rise in output per person employed since 1929, more even than the "advance of knowledge," and more than any single source, excepting only the increase in the labor force itself, to the increase in aggregate output. If we may trust the calculations, their implications for economic policy—at least when we have our eye on long-term results—are dazzling. My own reluctant conclusion, however, is that we cannot rest our faith in the importance of education for economic growth on these figures. They are subject to question at each important point.

First, the basic table of differentials by level of education is itself a weak basis for the calculation. At best, it gives us a reading on educational differentials at one point in time. The data on which it is based reflect "response errors which abound in the reporting of income and education in household surveys and censuses . . ." [6, p. 963]. The census data appear in the form of medians for age-education-income classes which need to be transformed by estimation into means. Variability of income around the estimated means for each age-group classified by educational level is large [3, Table 1]. Given the small size of the samples in many of the cells, the question arises whether the mean figures are, in fact, representative or biased by accidental differences due to type of education, quality of schooling, occupation and other factors.

Secondly, the adjustment to allow for the influence on the observed differentials of factors extraneous to education, while presumably necessary, is admittedly arbitrary. No one can say whether Denison's 40 per cent adjustment is too large or too small and by how much.

Thirdly, the distribution of the male population by level of education for years before 1940 is accomplished by cohort analysis based on 1940 Census reports in which it appears that older age-groups overstated their educational achievements to a degree that varies positively with age. Denison adjusts for this bias (which would have resulted in an understatement of the rise in the level of schooling) on the basis of its indicated importance in the decade 1940 to 1950. The indicated adjustment (0.81 percentage points per decade) amounted to 18 per cent of the calculated contribution of education to average earnings in the decade 1940-1950. But the importance of the adjustment in earlier decades, when the contribution of education to earnings change was smaller, would have been relatively still more important.⁹

Fourthly, the apparent importance assigned by Denison to the rise in level of education is approximately doubled by the fact that he treats the rise in school days per year on a par with the rise in number of school years completed. Denison offers no evidence to support his treatment, and I regard it as highly questionable.¹⁰

⁹ The relative importance of the same adjustment would have been 19.7 per cent for 1930-40; 24.6 per cent for 1920-30 and 30 per cent for 1910-20.

¹⁰ If I understand it, the procedure carries the absurd implication that a boy who com-

Fifthly, the Denison calculations are an incomplete accounting because they neglect changes in the quantity of on-the-job training and, more generally, of training outside formal educational institutions. Since the amount spent on such training is reported to be nearly equal to the amount spent on formal education,¹¹ changes in such expenditures would have a substantial bearing on the question.

Finally, whatever the accuracy and completeness of the Denison calculations, one should be clear that they take account of only that part of the return to education which is captured by individuals. Yet the difference between social and private product is probably very large and may be of the same order of magnitude as the private product itself. The progress of applied technology and the pace at which businessmen exploit it—including that part associated with the scale of markets—are surely significantly influenced by the number of scientists and the intensity of their schooling and by the level of skills in the population at large. The geographical mobility of the population and its adaptability to new forms of organization are also presumably substantial influences affecting the pace of progress which depend on the level of education in ways still hard to specify. Finally, the capacity of a democratic society to accomplish the transformations in its political institutions required to meet the evolving problems of a growing and rapidly changing economy also depends on the level of education of its people. Little of the return to education flowing through these channels can be captured by individuals. All of it is excluded implicitly or explicitly in Denison's calculations.

If these arguments are sound, we must conclude that Denison has probably not been successful in approximating the contribution made by the rise in the level of education to our past growth. His estimate of its private product is subject to a number of serious uncertainties and, perforce, he neglects the difference between its private and social product. According to his calculation, the contribution was very large; but it may have been much smaller or even larger, and we have no way now, so far as I can see, of saying what it really was.

Capital Input

As is well known, the measure of capital input is among the most vexed in the entire calculation. Consistent with his general procedure, Denison tries to obtain a series of capital inputs which will be proportionate to the product of the base-period earnings of capital and an index of the real capital stock. And, logically, the real capital stock is taken to be the cumulative sum of resources, valued at constant prices, devoted to saving diminished by "appropriate" sums

pletes eight years of elementary school today, when the number of school days per year is perhaps twice as large as it was on the average in 1910, has received the equivalent of a 1910 college education so far as effect on earning power is concerned.

¹¹ T. W. Schultz reports this estimate by Harold F. Clark and adds: "About all that can be said about on-the-job training is that expansion of education has not eliminated it" [9, pp. 9 and 10]. Apart from industry, the armed forces are an important locus of vocational training outside the schools.

because of depreciation or retirement. Denison defines the objective of deflation in these terms (p. 94): "The value in base period prices, of the stock of durable capital goods (before allowance for capital consumption) measures the amount it would have cost in the base period to produce the *actual* stock of capital in the given year (*not* its equivalent in ability to contribute to production)." And, with regard to capital consumption, he quotes Pigou: "When any discarding has occurred, in order to make good the depletion of capital implied in it, *that quantity of resources must be engaged which would suffice in actual current conditions of technique to reproduce the discarded element*" (Denison's italics, p. 95).

The net result of this procedure, if it could be implemented, would be to make the stock of capital move with the cumulative sum of saving in real terms, after appropriate depreciation, leaving changes in the quality or efficiency of capital goods to influence changes in output per unit of input, rather than the index of capital input itself. The actual means available for translating this conception into numbers are, of course, seriously imperfect. Raw data on capital formation (and hence the stock to which they cumulate), the figures underlying estimates of capital consumption, and the price deflators for both, all have serious limitations. The enforced neglect of the growth of government capital, for which there is no way to estimate earnings, is still another difficulty. It is surely among Denison's most valuable contributions that he threads his way so surely over this rough ground and explains the trail so clearly in this and other writings.

I confine my comments to a single point of principle. This is whether Denison (like Kendrick and his colleagues) is right in excluding the effect of quality change from his index of capital input and, therefore, in the frame of his calculations, from the estimated contribution of capital.¹² It is chiefly from this exclusion, coupled with the assumption that average earnings per unit of capital express capital's marginal contribution, that the generally rapid rise in the capital stock nevertheless accounted for only some 20 per cent of the growth in total output. Earnings of capital, taken over five-year periods, have been consistently small compared with earnings of labor. This was true even though the return to entrepreneurship is intermingled with the return to property. In Denison's calculations of total input, therefore, the rapid rise of capital stock is given only a small weight. The implicit moral is that the progress of output per unit of labor (adjusted for the contribution of education, etc.) has depended chiefly on the pace of advance in knowledge, on the skill of entrepreneurs in finding the best opportunities to use capital and labor, and on the efficiency of capital markets in channeling savings to business firms which are exploiting the best opportunities. The pace of advance would not have been

¹² There are other points which challenge discussion and, perhaps, debate, but alternative procedures would not greatly alter Denison's results and lack of space prohibits comment. These issues include Denison's use of estimates of "gross" rather than net capital stock as an index of capital input, his reliance on measures of the capital stock available rather than on that employed, and his classification of the reproducible durable stock into three groups: farm, nonfarm residential, and other nonfarm, each weighted by its own earnings.

much slower—problems of demand generation being neglected—even if the level of capital formation had been much lower. By the same token, acceleration of growth in the future, if it were to be accomplished by higher levels of investment alone, would require relatively huge increases in investment quotas.

The economic model which underlies Denison's calculations stands in sharp contrast to the model with which Robert Solow has been experimenting in his attempts to develop an aggregate production function for this country [10]. Solow asks us to imagine an economy enjoying advances in knowledge, potential economies of scale, extensions and improvements in schooling, improvements in social and economic organization and other elements of progress, all at some constant rate. But he assumes that none of these advances can be exploited except through the use of newly designed durable capital equipment. On the other hand, each unit of capital equipment carries with it a certain factor of improvement compared with equipment of older vintages, and this improvement factor is independent of the level of investment in a given year. In such an economy, given the improvement factor, the pace at which labor productivity advances would depend on the pace at which old capital is retired and replaced by capital of modern design and on the amount of capital of latest vintage added to the stock. In short, it would depend on the volume of gross capital formation. In calculating a production function which gives quantitative expression to this interpretation of U.S. growth, Solow finds, in effect, that the contribution of capital input to output growth is much greater than Denison does. An issue of first-rate importance is, therefore, posed.

In the issue thus drawn, it is well to be clear about what Solow is saying. He is not contending that capital formation is a sufficient condition for growth. The advances of knowledge, the economies of scale, the longer schooling, the improvements in organization were all necessary. Given their existence, however, Denison would have it that we could have enjoyed the greatest part of the observed increase in national product per man even if net capital formation had been zero. On Solow's calculations, however, the growth of national product is very sensitive to the accumulation of capital. If it had proceeded more slowly, the pace of advance of national product would have been greatly retarded. Capital accumulation was not a substitute for anything, or anything much, but it was the vehicle of everything.

So far as I can see, the difference between these two views depends crucially on the question whether improvement from whatever source can impinge on output per man only through the mediation of capital equipment of new design. As to this, it is common ground that the requirement that all improvement be "embodied" is not literally valid, and Solow makes no claim that his econometric work constitutes a test of the relative merits of his and a Denison-type model. By contrast with the literal requirements of Solow's model, Denison offers the judgment that the largest part of the actual changes in equipment design has as its object changes in the character of final products whose contributions to economic welfare do not register in measured national product. Contrariwise, Denison argues that as much as one-half of the productivity change which takes the form of reductions in cost actually reflects managerial and organizational improvements requiring little or no changes in equipment.

Moreover, in so far as new capital was required to carry productivity change, it was a vehicle for somewhat less than one percentage point in the growth rate in recent decades, not for the whole increase in man-hour productivity—some 2.5 per cent per annum—as in Solow. The factual gap between the two views is, therefore, profound and not really usefully attacked by speculation. Still further issues arise when we consider the implications of the Denison and Solow analyses for growth policy [see below].

Output per Unit of Input

In earlier calculations of the kind Denison makes, the difference between the number of percentage points in the rate of growth of the index of combined inputs and that in the rate of growth of national product represented an unanalyzed residual. It was larger than Denison's measure of productivity change because it included the contribution of certain unconventional inputs which Denison has isolated in the form of changes in the quality of labor associated with the rise in the level of education and with that in intensity of effort. But Denison does not leave even the smaller figure which he derives as the difference between input growth and output growth as an undifferentiated residual. He makes explicit allowance for two broad classes of factors: changes in the efficiency of resource allocation and economies of scale.

Denison treats changes in the efficiency of resource allocation under a dozen different heads. Each taken separately appears to have had only a small influence on the growth rate in past decades. According to Denison's estimates, their effect would have been minor even if they had all operated in the same direction. It appears, however, that they did not, and in Denison's tables, their net effect during the last three decades emerges as zero. I see no reason to doubt that Denison's estimates are of the right order of magnitude. For good or evil, changes in the efficiency of resource allocation have not been an important growth factor in this country. It is worth remembering, however, that the kinds of factors Denison takes up as having a bearing on resource allocation have other consequences for growth which may be far more important, but which inevitably escape our statistical net. Thus, in considering the tax structure, we cannot account for its impact on the level and composition of investment. In considering the restrictions on competition, we have to neglect their influence on the inducement to engage in research and to hunt out and exploit new methods of production and improved final products. In considering international trade restrictions, we have to pass over their significance for competition and for the flow of information about production processes and methods of industrial organization. Denison does, indeed, make perceptive comments about all these influences, but, quite understandably, he finds no way to measure them, and he leaves them all to be reflected in his ultimate residual.

By contrast with resource allocation, the economies of scale appear, in Denison's tables, as a principal source of growth, accounting for some 37 per cent of productivity growth during 1929-57 and for fully 50 per cent during 1909-29. Unfortunately, the estimate for this undoubtedly important factor hardly bears discussion. The considerable figure Denison assigns to it is merely the

numerical expression of an assumption that the economies of scale due to the growth of the national market yielded an advance in output equal to one-tenth that yielded by all other growth factors (that is, one-eleventh of the increase in measured national product) and that economies due to the independent growth of local markets were one-tenth as large. But this assumption is based on no empirical evidence whatever and, as Denison makes amply clear, constitutes no more than his own sober judgment. A good man's sober judgment is not to be spurned. I know of no theoretical or empirical considerations which render it doubtful, but, like Denison, I know of none which makes it seem particularly trustworthy. I take it that the explicit recognition of this factor in Denison's table chiefly serves to remind us that there is such a factor which needs to be taken into account when one considers the contribution to growth made by changes in other forces.

It is only after providing for the two classes of influences just mentioned that Denison comes to his ultimate Residual. He calls it the "Advance of Knowledge," but, of course, this category, which nominally accounts for just 20 per cent of total growth during 1929-57, is not in any meaningful sense a measure of that alone, and it may not be a measure chiefly of that. For, as a residual, it is the grand legatee of all the errors of estimate embodied in the measures of national product, of inputs conventional and otherwise, and of the economies of scale and other factors classified under productivity growth. Beyond this, however, several points of principle deserve notice and discussion.

First, as Denison clearly explains, the figure set down for the Advance of Knowledge is not the full contribution of that factor—whatever it may really be—to the growth of national product considered as a measure of economic welfare. For national product, as measured, neglects much or most of the change, conventionally taken to be improvement, in the quality of final products. Since such change does not affect the measure of inputs, any adjustment for quality change in the measure of national product growth would add the same amount to the measure of the Advance of Knowledge. Indeed, it is Denison's view that a very large part of that advance, particularly in the form of technical progress, is in fact devoted to the discovery and production of new final products not reflected in the national product estimates.

Second, the Denison residual still reflects the contribution of certain inputs, chiefly expenditures to support research and development activities and expenditures for education in so far as these help provide the scientific and technical personnel for research and the skilled labor whose presence encourages firms to exploit the advance of technology.

Finally, however, we have to recognize that, even apart from errors, the residual cannot be regarded as the contribution of the advance in knowledge in any meaningful sense. It is, in fact, nothing more and nothing less than the measure of the advance in productivity from every source other than those specifically identified elsewhere in Denison's calculations. The issue can, perhaps, be brought to a focus by considering the distinction made by Denison between what he calls the advance in knowledge and what he calls the "lag in the application of knowledge." The latter he considers can be measured by,

though it is not identical with, the change in the average age of capital goods, a consideration which turns out to have been a negligible growth factor in recent decades. This identification for purposes of measurement, however, suggests that there is some stable relation between the techniques embodied in the capital stock added in a given year by firms who invest that year and the best techniques which are, in some sense, "available" in that year. What sense should that word "available" be given?

(a) Is it to mean the best techniques which the basic principles of the physical universe as apprehended at a given time, together with the existing empirical information, make possible, regardless of the expense and work involved in translating the basic principles into appropriate applied forms and communicating that knowledge to all concerned, and regardless too of the institutional obstacles involved in obtaining finance and labor or of the will and incentive to overcome these obstacles?

(b) Or is it to mean, say, the techniques adopted by the most advanced firms in each year (in the United States alone? anywhere?)? This criterion would take into account the existing problems of information, entrepreneurship, finance, labor supply, legal and market restrictions as faced by the most advanced firms in a given year.

(c) Or is it to mean, as I think it does mean for Denison (and, in the present state of our estimates inevitably must mean) the techniques available to representative firms which actually do invest in a given year, having regard to the representative state of entrepreneurial capacities, drives and outlets and to representative conditions governing information, labor supplies, finance, and so forth.

It goes without saying that the last criterion is tautological since it identifies the Advance in Knowledge with the improvements actually made. Denison's ultimate residual is, therefore, inappropriately titled. Errors aside, the size of that residual must be taken to reflect the effective rate at which actual progress in techniques of production takes place in representative firms. Certainly its connection with the advance of knowledge conceived of as some disembodied stock of principles and factual information is indirect and uncertain.

No one who reads Denison on the sources of U.S. growth can fail to benefit. His discussion of the conceptual and statistical problems involved in estimating the contributions of various sources can only be described as a tour de force. So far as that goes, his book is an epitome of years of work and writing by himself and by many other students of national income and productivity measurement. In Denison's hands, the subject emerges again pithy, fresh and forceful. Nevertheless, it seems to me that the fruits of all this work have not yet ripened. The problem posed by Schmookler and by Kendrick and his National Bureau colleagues—namely, that to explain a very large part of the growth of total output and the great bulk of output per capita, we must explain the increase in output per unit of conventionally measured inputs—still remains. We can draw up a catalogue of the kinds of elements of which such an explanation must be composed: unconventional inputs, like labor intensity and education; economies of scale; and advances in knowledge of techniques and

organization. Denison's attempt to attach numbers to these elements, however, still falls short of success. And this unfortunate fact is just the inevitable consequence of the present state of the art. The underlying data are weak, the various growth factors interact in a complex way (and expand along distressingly parallel lines), and experiments with the statistical derivation of production functions have really just begun.

II. *The Alternatives Before Us*

In this review, I have followed the lead of Denison's title (which prints SOURCES in caps and Alternatives in caps and lower case) by devoting most of my space to Sources. It is probably true, however, that Denison's interest in the analysis of history is largely subsidiary to his interest in the formulation of policy. Nevertheless, I must now deal with the policy side of his work in summary fashion. I can, perhaps, do this the more easily because I can agree with so much of what Denison has to say.

If I read him right, Denison's general conclusion is that, for the United States, acceleration in growth cannot be sought only along a few very broad lines of policy. If we are to raise our measured growth rate significantly above the level it would achieve without deliberate social intervention, we must take action along a great many lines, each of which taken by itself can make only a minor contribution. In Denison's view, the country would be hard put to devise and implement a set of policies likely to raise our rate of growth per annum during the period 1960-80 by a full percentage point above what it would otherwise be. Yet, if we were determined, such a set could be found from among the many alternative policies open. And a one percentage point increase would be no mean achievement since it would imply a rate of aggregate growth about one-third higher than Denison's projected autonomous rate and a 50 per cent rise in the rate of growth of per capita income relative to the same standard. Subject to some comments at the end of the paper. I agree with this general position, and I think its strength can best be brought out by reviewing Denison's appraisal of four lines of policy that have attracted attention.

One is to increase *the rate of growth of the labor force*. Since past births have already determined the native-born population from which the labor force can be drawn, only three possibilities remain: to increase participation rates, to slow down the decline in hours of work, and to increase the flow of immigrants. Maintaining conditions of full employment is often held out as likely to have a favorable influence upon participation rates and hours. However, Denison surely is right in saying that the difference between the average level of unemployment maintained since the war and that at which a successful full employment policy might aim would have a small and uncertain effect on participation rates.¹³ The opportunity to influence working hours seems

¹³ Denison (pp. 661-66) argues persuasively that J. W. Knowles' view [5] that, if unemployment rates are maintained at 3 per cent rather than 5 per cent, the labor force might grow at 1.9 rather than 1.5 per cent per annum, greatly exaggerates the possibilities. If Knowles were right, the 1975 labor force would be 5.9 million persons, or 6.5 per cent larger if the unemployment rate stayed at 3 per cent in the interim than if it stayed at 5 per cent. But this would imply an enormous difference in the participation of women and elderly persons, since there is little room for variation in the participation of males in their prime working years.

brighter, and Denison considers that a successful full employment policy would help to reduce the anticipated decline in hours. We might make limited gains in this way. If we could reduce the anticipated decline by 25 per cent, or one hour per hour-week, this would increase our growth rate by 0.1 percentage point per annum. What we can do by way of immigration is, of course, entirely a matter for national choice. Yet, even doubling the rate of immigration would add only 0.1 point to the growth rate, allowing something for the generally lower quality of immigrant workers.

Education to improve the quality of representative members of the labor force is a second possible source to which many look for more rapid growth during coming decades. It seems clear, from Denison's calculations, however, that little can be expected from this source in so far as its contribution depends on the quantity of education. A crude calculation tells one reason why. From 1930 to 1960, when—by Denison's figures—increased levels of education were increasing output per man almost one per cent per annum, the average number of school days attended by workers in the labor force was rising about 20 per cent per decade. The projected increase in school days attended during the next 20 years is somewhat smaller, but still large, roughly 16 per cent per decade. The drop is due to a combination of an expected smaller increase in the number of years attended by representative youngsters now in, or expected to enter, school, and a still smaller increase in the length of the school year, counterbalanced by the entrance into the labor force during the next decades of many younger workers who benefited by the great extension of education during the last few decades. The result would be a rate of increase in output per man almost, but not quite, as great as in previous decades. However, as the effect of past educational reforms makes itself fully felt with the graduation of young people into the labor force, it will be increasingly difficult to maintain the contribution of longer schooling to labor output. The school year is already quite long. In the aggregate, the possibilities of extending the contribution of education at the high school level is running out because the percentage of young people completing high school is already very high. Thus the pace of advance would have to be sustained largely by a great expansion of college and university education alone. In the long run, it seems inevitable that the contribution of education to growth must fall.

Apart from the physical difficulties of continuing to raise the amount of schooling at even its old pace, the effect of additional schooling on labor output is a very long-run effect. What we do now to increase years of schooling will be of little consequence until, after some decades, a large proportion of the labor force with less schooling has been replaced by men and women with more. One need not accept Denison's estimates of the returns to schooling in order to see the force of these considerations which seem to me to be among the most cogently argued portions of his book.

All this is not to say that longer education would not benefit certain underprivileged groups greatly, or that expenditures to make more education more widely available are not of the greatest importance simply to sustain present growth rates during the next decades and to provide for somewhat more rapid advance in the still longer run. It does mean, however, that if education is to

make striking advances to accelerated growth of output, it probably will have to be through improvements in the quality of education, through better selection of the most able students for higher education, and through concentration on those courses of study the importance of which, for increased output is particularly high.

An increase in the proportion of gross national product devoted to *capital formation* is regarded by many as the key to more rapid growth. Two questions arise: how to raise the level of investment; and how much benefit we might obtain from a given increment of investment.

Denison's discussion of the first question is knowledgeable and sophisticated, but not particularly novel. The way in which the brew of monetary policy, fiscal policy, redistribution of tax burdens, the treatment of depreciation, etc., might be mixed has engaged the attention of many cooks. Economists will find Denison's recipes carefully considered but familiar. They are unlikely to make anyone sanguine about the possibility of obtaining dramatic results. And dramatic results are what would be needed, for—as we already know—additional capital accumulation, according to Denison, is likely to contribute much less to growth than many suppose.

On this point, Denison's views are challenging. They flow simply and directly from the proposition—a deduction from marginal productivity theory—that, say, a one per cent increase in capital input will raise national product by only that fraction of one per cent which is given by the share of income going to capital. Since the share going to capital is small, while the capital stock is several times as large as national product, it is obvious that the order of magnitude of the additional net investment required to increase national product by, say, one per cent is very large indeed. On Denison's calculations, additional net investment would have to be in the neighborhood of 13 or 14 per cent of national income if the composition of the new investment were similar to that of the existing stock.¹⁴ This would involve raising the ratio of net investment to national income to 3.3 times its present level.¹⁵ Simply to raise the growth rate by 0.1 per cent during the next 20 years would mean raising the net investment ratio by about 25 per cent. These figures reflect Denison's allowance for returns through economies of scale, but they make no allowance for diminishing returns. For massive injections of additional capital per worker, the allowance required on this latter account might well be substantial, as Denison points out, and even his large figures for the additional investment needed to raise growth rates would then be too small.

It is an implication of Denison's analysis that we might do much to stimulate growth without raising our investment quotas. We might even permit them to sink, but in order to stimulate growth significantly through capital accumulation we should have to increase our investment quotas enormously. The moral of Solow's view is just the opposite. Pressed to the limit, nothing we might do to stimulate growth would be effective without a good deal of investment. But

¹⁴ The figure would be in the neighborhood of 10 per cent if none of the additional investment were devoted to housing for which the return is low.

¹⁵ If none of the increment went to housing the required multiple might be lower—2.7, according to Denison.

if we could merely maintain the rate of *potential* improvement opened up by the advance of knowledge, the economies of scale, the extension of education, and whatever else contributes to the potential efficiency of resources, a fairly modest increase in rates of capital formation would provide large increases in our rate of growth. Additional investment would embody additional quotas of each year's potential productivity gains from all sources *pari passu*. But is Solow right?

We have already seen how the range of validity of his model depends on the degree to which potential productivity gains, whatever their source, require embodiment in capital of new design. As we look to the possible gains from enlarged investment quotas, additional questions arise, and Solow himself has identified them: "... a sharply higher rate of investment may bring about premature scrapping of old equipment. . . . [T]here may be limits even in a mature economy to the speed with which the system can adjust to large inflows of capital" (10, p. 86).

It is evident that even in what Solow calls "the prosaic case of tangible capital formation," we are still a long way from having quantitative estimates of the social return to resource input.

Finally, I note briefly, Denison's treatment of the potentialities of expenditures for *research and development*. The great hopes that are sometimes placed in the efficacy of enlarged expenditures for this purpose are swiftly cut to more modest dimensions by Denison's scalpel. How much, he asks, of the .58 percentage points in the measured growth rate which he assigns to Advance of Knowledge can be attributed to organized R and D? The knowledge relevant to measured growth is that which lowers costs, not that which yields new final consumer goods. In large part such knowledge consists of managerial and organizational procedure rather than technology proper, and some part of technology is an engineering by-product of ordinary production activity. Suppose one-half the relevant advance is technological, that one-half of this stemmed from activity in the United States, and that two-thirds of this came from organized R and D. Then one-sixth of the .58 percentage points is assignable to R and D in this country. The factor Denison applies is one-fifth, so his answer is .12 percentage points. Denison calculates that the expenditure which is to be associated with this result may be gauged from the \$5 billion for privately financed research in 1960 of which some portion was devoted to style changes and other adaptations of only transient influence. Since Denison estimates that it would have required about \$3.8 billion of net investment devoted to nonresidential capital to raise national product by the same .12 percentage points, he concludes that the social return on the two classes of expenditure was about the same and that neither was high.

Such calculations are, of course, no more than guesswork,¹⁶ yet useful in es-

¹⁶ One possible flaw in the argument, however, may be worth notice. If there is any substantial lag between R and D expenditure and its results, the contribution of .12 percentage points to the growth rate should not be associated with expenditures of the same date. Five years earlier, such expenditures in current prices were one-half as large and ten years earlier perhaps one-fifth as large. The difference in constant prices would have been smaller.

tablishing orders of magnitude. An important reason for this apparently modest return is that the bulk of R and D—perhaps $\frac{1}{2}$ of private and virtually all government expenditures—is devoted to product improvement, which does not register in measured national product, but which we want. We, therefore, have every reason to encourage R and D, but little reason to expect dramatic results in terms of measured growth. This is all the more true if Denison is right in thinking that resources devoted to research operate subject to rapidly diminishing returns to scale. He finds no evidence that the pace of Advance of Knowledge has been growing even as fast as our population, much less as fast as the scientific personnel and capital specially involved.¹⁷ On the other hand, there is no reason to accept the present outlay of funds devoted to applied research as even approximately as good as it might be. In an activity where the difference between private and social return is so great and where the returns private firms can capture are so heavily dependent on the size of firms, the character of markets, and the nature of the product, there is little reason to trust ordinary market incentives to guide the allocation of funds. Actual expenditures are, in fact, highly concentrated in relatively few industrial sectors, and in some are virtually neglected. There may well be opportunities to increase the productivity of resources devoted to research by a wider distribution of expenditures, as Denison cogently argues.

The general moral of Denison's book is that those who seek more rapid growth for the United States must pursue it along many lines. There are no three or four broad measures which, if taken, promise dramatic success. Denison himself offers a shopping list of 31 possible lines of action from most of which we should be hard put to extract an extra 0.1 percentage point for the growth rate. Some might be pressed for more, some do not offer even that much, some would affect only "true" rather than measured growth, some might be judged undesirable for one reason or another.

I suspect that this hard moral of Denison's book is sound. Yet it is also clear that the knowledge on which such a judgment is based is extremely weak. Denison has made a wholly admirable effort to reduce the problem to quantitative terms, and the authority with which he handles the data, the skill and judgment with which he uses them, are evident from first to last. Yet, on close inspection, I think the figures fall apart at almost every important point. In spite of the author's careful and candid exposition, there is a certain air of reliability and precision about his estimates which the state of our knowledge today simply does not support.

We are, indeed, just at the beginning of serious work on the subject of economic growth in the United States. Denison's important contribution is to have pulled the many parts of the problem together and built a structure with such shape and solidity as the materials now permit. Doubtless as the work advances, more complex and subtle models of our economy will be designed, and

¹⁷ This is a judgment manifestly subject to the ambiguities surrounding Denison's identification of his Residual with Advance of Knowledge.

statistical estimation will have to rest on more advanced econometrics than Denison employs. The pace at which useful work can proceed will depend in good part on the appearance of more reliable and detailed information. There is, in fact, almost everything yet to be done, but those who want to contribute to the subject can hardly do better than to take their start with Denison.

The Analysis of Demand

The first part of this paper attempts to construct a more complete, more systematic and more symmetrical formulation of the Hicksian analysis of demand. The second part endeavors to integrate substitution effects, income effects and complementarities in a more general alternative approach to the analysis of demand.

I. *A Suggested Reformulation*

John R. Hicks' valuable separation of demand into income effects and substitution effects [2, Ch. 2] and his analysis of the substitution effect into complementarity and substitution [2, Ch. 3] are difficult for students to handle, partly because of a certain unnecessary asymmetry and partly because of the use of the word "substitution" for two different purposes.

The asymmetry occurs in the dichotomy of goods into the rather special class of "inferior goods," of which one buys less when real income is increased (relative prices remaining the same), and the much more general class of all other goods. A symmetrical dichotomy might be to divide goods into those which increase less than in proportion to the increase in income and those which increase more than in proportion. Hicks' segregation of inferior goods is more useful than this symmetrical dichotomy, but the benefits of segregating inferior goods could be retained in a more complete and yet symmetrical analysis that marked off a "normal" area from "inferior goods" at one extreme and "superior goods" at the other extreme. A parallel asymmetry appears in Hicks' dichotomy of the substitution effect into complementary goods and all other goods which he calls substitute goods. Here, too, a trichotomy could separate out an opposite extreme, symmetrical with complementarity, leaving a middle range between the two extremes.

The other difficulty that sometimes confuses students is Hicks' use of the same root both in the term "substitution effect" to refer to the change in the amount of a good bought in response to a change in its relative price (as contrasted with the "income effect" or the response to a change in real income) and in the term "substitute good" to refer to a particular kind of substitution effect; namely, the effect of a reduction in the amount of one good bought when more of another good is bought (as contrasted with a "complementary good" where there is an increase instead).

To avoid these difficulties I suggest the following set of nine definitions:

1. *Income effect*: The change in the quantity of good¹ bought as a result of change in real income, relative prices remaining the same.

¹ Throughout this article, "good" stands also for any *group* of goods whose relative prices are unchanged.

2. *Inferior good*: A good of which less is bought (and therefore has less income spent on it) when income increases. (Income elasticity of demand is negative.)

3. *Superior good*: A good of which so much more is bought when income increases that more than the whole increase in income is absorbed (and less is therefore left available to be spent on everything else). (Income elasticity of demand is greater than the ratio of total income to the amount spent on the item.)

If any good is inferior, then the remaining good (or all the remaining goods taken together) must be superior because more than the whole increase in income is left to spend on it; and conversely, if any good is superior, the remaining good (or all the remaining goods taken together) must be inferior because there is less income left for it (or them).

4. *Normal good*: A good of which more is bought when income increases, but not so much more as to leave less income for everything else. (Income elasticity of demand is positive, but less than the ratio of total income to the amount spent on the item.)

It is possible for all goods to be normal, but they cannot all be inferior and they cannot all be superior. These relationships are illustrated in Figure 1 where the arrows represent possible directions of movement in the quantities of X and Y bought as income is increased from the initial point P .

FIGURE 1

The NE quadrant (with respect to P) shows the case when X and Y are both normal so that more of both is bought when income increases. The NW quadrant shows X inferior and Y superior. The SE quadrant shows Y inferior and X superior. The dotted arrow passing through P from the origin is the symmetrical dichotomy suggested above, but rejected in favor of the trichotomy into inferior, normal and superior. In terms of the dichotomy, an arrow through

P steeper than OP would show Y superior and X inferior and a flatter arrow would show X superior and Y inferior, leaving no area at all for "normality."

Hicks' formulation distinguishes only between the NW quadrant where X is inferior and all the other possible directions for the arrows where X is not inferior. It can also be applied in reverse to distinguish only between the SE quadrant where Y is inferior and all the other possible directions of the arrows where Y is not inferior.²

If a group of goods taken together is inferior (i.e., less is spent on them when income is increased), not all of the goods in the group have to be inferior individually. Some of the individual goods and some subgroups may increase in quantity (and therefore have more spent on them) when income increases—i.e., they may be normal or even superior. But at least one of them must be inferior. If less is spent on all of them together, but more than before is spent on some of them, it must be even more true of the remaining ones that less than before is spent on them.

If a group of goods is superior, it is similarly true that not all of them have to be superior individually. But in this case it is possible that no member of the group and no subgroup will be superior. All the members of a superior group and all the subgroups may be "normal" in that although more of each is bought (and more spent on it than before) no single one has more than the whole increase in income directed to the increased expenditure on itself, and some may even be inferior.

To avoid one of the uses of the word "substitution" while refining the analysis of Hicks' "substitution effect," we shall speak instead of direct and indirect price effects.

5. *Direct price effect*: The effect of a change in the price of a commodity on the quantity of that commodity bought (the real income level being kept constant by an adjustment of money income).

The direct price effect is always negative, i.e., the quantity change (if any) is in the opposite direction to the price change. The cheapening of a commodity can never by itself result in less of it being bought.³

6. *Indirect price effect*: The effect of a change in the price of a commodity

² Students (and teachers) are frequently tempted to say "superior" for noninferior and to suppose that in this they are following Hicks. Hicks does speak of "the inferior good and the superior substitute which replaces it" [1, p. 66], but only to refer to a particular substitute, and does not call "noninferior" goods in general "superior goods."

³ Prestige goods are only apparent exceptions. If the only thing that is reduced is the price that actually has to be paid, more, never less, will be bought. A change in the price that other people *think* you pay can work the other way, but that is not a genuine price effect.

Similarly with the case of expectations. If price reductions establish an expectation of further reductions, purchases may drop, but it is not the reduction or what one actually has to pay that is responsible for this. It is the *expectation* of future price reduction that is responsible. Such an expectation would be only *more* restrictive if it were not for the reduction in what actually has to be paid. In the case of an inferior good, too, the reduction in what has to be paid for additional units can only be responsible for *increasing* the amount bought even if the income effect (of the money saved by the price reduction) should more than offset this in a "Giffen" case.

on the quantity bought of *another* commodity (the real income level being kept constant by an adjustment of money income).

In the case of two commodities only, the indirect price effect can only be positive, i.e., the quantity of the other commodity must move in the same direction as the price of the first commodity. If X becomes relatively cheaper and more of X is bought, this must be accompanied by a decrease in the amount of Y if the real level of income is not to go up; and conversely, a rise in the relative price of X which reduces the amount of X bought must be accompanied by an increase in the quantity of Y .

In the case of more than two commodities, three cases are possible: complementarity, its opposite, and competitiveness.

7. *Complementarity*: If more of Y is bought when more of X is bought (because X has become cheaper), then Y is complementary with X .

If Y is complementary with X , X must also be complementary with Y . More of Y is bought only if the increase in X makes Y more effective. This means that the effectiveness of X and Y together is greater than the sum of the effectiveness of each of them separately, and that means that an increase in Y makes X more effective and X is complementary with Y .

For example, suppose that initially X and Y each cost \$1 a unit and are used in such quantities that their marginal worth is just equal to their price. The price of X is then reduced to 90 cents per unit and the quantity of X is expanded until an additional unit is worth no more than 90 cents while the quantity of Y is held constant. If Y is complementary with X (so that there would be tendency for more of Y to be bought), this means that an additional unit of Y has become worth more than its price. Let us say it has become worth \$1.05. A unit of X and a unit of Y *together* are then worth at least \$1.95. (They would be worth more than this to the extent that adding another unit of X would increase the worth of Y still more.) This means that the use of an additional unit of Y (which costs \$1) raises the marginal worth of X from 90 cents to at least 95 cents and that means that X is complementary with Y .

Whenever Y is complementary with X , Z must be related to X in an opposite manner. If increase in X (due to a reduction in the price of X) is accompanied by an increase in Y , there will have to be a reduction in Z sufficiently great to keep the individual on the same level of real income even though both X and Y have increased. It may seem that the natural name for this relationship would be *substitution*, which suggests a natural counterpart to complementarity. This, however, will not do for two reasons:

(a) The counterpart to complementarity, like complementarity itself, is applicable only to the case where there are three or more variables. Yet, it is almost impossible to avoid using the word substitution when referring to the replacement of one input by another or of one output for another in response to a price change where these are the only two variables and complementarity and its counterpart cannot arise.

(b) The term substitution suggests that what is involved in the counterpart to complementarity is a very high degree of substitutability—i.e., that if Y is complementary with X , this is because so much of Z is displaced by the relatively cheapened substitute X that more of Y has to be brought in to main-

tain the level of real income. But the phenomenon we are concerned with cannot be explained by a high substitutability of X for Z . Even if we take the very highest conceivable degree of substitutability, namely the case where X and Z are completely identical items and therefore absolutely perfect substitutes, a cheapening of X results in Z being completely displaced by X . There would then be more of X than there previously was of X and Z together,⁴ because some additional X would displace some of Y (some X will be substituted for some Y). There would therefore have to be *less* Y than before so that Y could not be complementary with X . The relation between Z and X that is a reflection of complementarity between Y and X is not substitutability, but something basically different.

We must therefore avoid the word "substitution" and instead speak of "anticomplementarity."

8. *Anticomplementarity*: If, when X is cheapened and more of it is bought, so much less of Y is brought that there is more money left for Z (even though less money than before must be available for Y and Z together) then Y is anticomplementary with X .

There must be less money left for Y and Z together because if this were not so when we have more X , the real income level would be greater, and we are still assuming that money income is being adjusted so as to maintain the same level of real income.

If Y is anticomplementary with X , Z must be complementary with X since more of Z is bought when more of X is bought. (There is more money left to buy Z at an unchanged price.) The converse is also true. If Y is complementary with X , Z must be anticomplementary with X —i.e., so much less of Z is bought that more money is left for Y (otherwise more of Y could not be bought and Y could not be complementary with X).

9. *Competitiveness*: If less of Y is bought when more of cheapened X is bought, but not so much less as to leave more money for Z , then Y is neither complementary nor anticomplementary with X , but a competing good.

It is possible for all goods (other than X) to be competing with X , but it is not possible for all to be complementary with X or for all to be anticomplementary with X because, as we have seen, if Y belongs to either of these last two categories, Z must belong to the other, and vice versa.

A group of goods that is complementary with X may contain goods and subgroups of goods that are not individually complementary, but competing or even anticomplementary with X . In that case, the remaining goods as a subgroup must be even more complementary with X . Since more than before is spent on the complementary group as a whole and less than before is spent on the competing and anticomplementary goods within the group, there must be a still greater increase in the amount spent on the remaining members of the group. At least one of its members must therefore be individually complementary with X .

A group of goods that is anticomplementary with X may similarly contain members of a subgroup of members that are not anticomplementary, but

⁴There is no difficulty in making this comparison because if X and Z are perfect substitutes, an appropriately chosen unit of X is exactly equivalent to a unit of Z .

competing or even complementary with X . But, in this case, it is possible for *none* of its members or subgroups to be anticomplementary with X individually. If some are complementary (so that more is spent on them than before), the remaining members, as a group, will be even more anticomplementary with X . But all the members of any anticomplementary group may be competitive, in that although less is spent on each member than before, no single member or subgroup (which we may call Y') has so much less spent on it that more money is left for Z' (the group of all goods other than X and Y'), and some may even be complementary.

Hicks' "income effect," "inferior good," and "complementarity" have the same meanings as here. Hicks' "normal good" may be either a superior good or a normal good, his "substitution effect" may be either a direct price effect or an indirect price effect, and his "substitute good" may be either an anticomplementary good or a competing good.

II. *Substitution Effect: An Alternative Approach*

The following device is an attempt at an alternative approach to Hicks' "substitution effect." It tries to combine the symmetrical dichotomy mentioned in the beginning of Section I with the trichotomies developed thereafter and it grows directly out of Hicks' extension of the analysis of consumption to the analysis of production. It yields a more general formulation that assimilates income effects to the price effects.

Definition 1—An *element* is an input or an output, outputs counting as positive elements and inputs as negative elements.

Definition 2—A *variable element* is an element that varies in quantity in response to price changes.

Theorem 1—In any economic situation, the changes in the variable elements in response to a change in the relative price of a variable element will never all be in the same direction. If one element increases, at least one other element will decrease, and vice versa.

This is because in any economic situation an increase in an output must be accompanied either by a decrease in some other output or by an increase in some input (which is a decrease in an element, inputs being counted negative). Similarly, a decrease in an input (which is an increase in an element) must be accompanied either by an increase in some other input or by a decrease in some output. If this is not so, the original situation must have been an uneconomic one in which it was possible to get something for nothing. Conversely, a decrease in all the elements that varied would indicate a deliberately wasteful decrease in output or increase in input, implying a departure from an economic situation if such a situation existed in the first place. This theorem seems to correspond to the elimination of income effects by fixing the "nonvariable" elements that constitute the framework within which we are working, leaving room only for relative price effects on the variable elements. (We shall see below that this is not quite so.)

Definition 3—The *direct price effect* is the effect of a change in the relative price of an element on the ratio between the quantity of that element and

the quantity of all the other variable elements taken together. (This corresponds to definition 5 of Section I.)

Theorem 2—If the prices of the variable elements all change in the same proportion, so that there is no *relative* change in their prices, there will be no effect on the quantities of any of them.

Since there is no change in the relative price of any pair of variable elements, there is no reason for substituting one for another or for changing the rate of transformation of one into another. A proportional change in the prices of all the variable elements does mean a proportional change in the opposite direction of the relative prices of all the fixed elements relative to the prices of the variable elements, but the quantities of the fixed elements, by definition, cannot be changed.

Theorem 3—Any direct price effect is always positive. The quantity of the element changes in the same direction as the relative price absolutely, as well as in relation to the other variable elements.

This means that a cheapening of an input relatively to the prices of the other elements, if it has any effect at all, will always result in an increase in that input (which is a decrease in the element), and that an increase in the price of an output if it has any effect at all will result in an increase in its output. (The changes might be very small or, in the limiting case zero, but never in the opposite direction.)

Theorem 4—Any response to a change in the price of one variable element in the quantity of the other variable element (or in the quantity of all the other variable elements taken together if there is more than one) is always negative; the quantity—absolutely as well as relatively to the first variable element—changes in the direction opposite to the change in the relative price of the first variable element.

This is because the change in the relative price of the first variable element constitutes an opposite change in the relative price of the second variable element (or the group of all the other variable elements) and the positive direct price effect of the latter constitutes a negative response to the first price change.

Where there are only two variable elements, these relationships can be expressed as follows:

(a) Where both of the variable elements are inputs, e.g., factors of production, one will be substituted for another if its relative price falls. Our device here merely changes the sign—the increase in the relatively cheapened factor is a decrease in one element, and the decrease in the other factor is an increase in the other element.

(b) Where both of the variable elements are outputs, and the price of one output rises relatively to the price of the other, the first will be substituted in production for the second.

(c) Where one of the two variable elements is an input and the other is an output, we find ourselves dealing not with substitution, but with increases or decreases in *production* (the transformation of one element into another). An increase in the price of the product (or output) relatively to the price of

the factor (or input) will result in an increase in the output of the product (an increase in one element) accompanied by an increase in the input of the factor (a decrease in the other element); and conversely for an increase in the relative price of the factor.

Where there are more than two variable elements, we may treat the situation in the same way by considering all the other variable elements (other, that is, than the first, whose relative price has changed) as a single second variable element.

This gives no trouble where all the other variable elements are outputs (which have the same sign as elements) or where all the other variable elements are inputs (which have the opposite sign). The matter is a little more troublesome where some of them are outputs and some are inputs. In that case, an increase in the quantity of the "second element" will consist of the increase in the value of the outputs minus the increase in the value of the inputs (or plus the decrease in the value of the inputs), all of course weighted by their unchanged prices.

If the change in the quantity of the first element is accompanied by opposite changes of exactly the same proportion for every one of the other elements, so that the ratio between these is unaffected, it is obvious that they can be treated as a single item and that is the end of the story. Only the direct price effect is operative. But a change in the price of one element, and the consequent change in the ratio of this element to the others taken together, may have an *indirect* effect on the proportions between the other elements. Thus, if the variable elements are all inputs, a decrease in the price of input *A*, while bringing about the substitution of *A* for other inputs, may also result in a second input *B* being substituted for the remaining inputs (which we may now consider together as a third input *C*). The same indirect effects are of course also possible if the elements are outputs or if some are inputs and some are outputs.

Definition 4—The *indirect price effect* is the effect of a change in the relative price of one variable element on the proportion between a second variable element and the remaining variable element of elements. (This corresponds to but is different from definition 6 of Section 1.)

The direct price effect can be measured by the (direct) elasticity of substitution (or by the elasticity of transformation) which is the proportional change in relative price divided into the proportional change in the relative quantities of the two elements, or groups of elements) involved.

The indirect price effect can be measured by the *cross*-(or indirect) elasticity of substitution (or transformation) which is the proportional change in the relative price of the first element divided into the proportional change in the ratio between the second and third elements.

If *A*, *B*, and *C* are the variable elements, the direct elasticity of substitution or transformation (the measure of the direct price effect of a reduction in the relative price of *A*) is equal to the proportional change in the relative price of *A* (relatively, that is, to the prices of *B* and *C*) divided into the proportional change in $A/(B + C)$, when $(B + C)$ is the value of the combination of *B* and *C* measured at their old prices. The cross-elasticity of substitution or trans-

formation (the measure of the indirect price effect) is equal to the proportional change in the relative price of A divided, not into the proportional change in $A/(B + C)$, but into the proportional change in B/C . If this measure is positive for B , it is negative for C and vice versa, with a dividing line where both are zero and there is no indirect price effect.

The indirect price effect becomes particularly interesting when it is so great that it is able to reverse the direct price effect on the quantity of one of the "other" elements (i.e., other than the one whose relative price has changed). This will be the case only if the increase in, say, B on account of the indirect price effect (i.e., its being substituted for C) is greater than the decrease in B on account of the direct price effect (i.e., greater than the decrease in B that would have taken place if there had been no indirect price effect and the decrease in $(B + C)$ had consisted of exactly proportional reductions in B and in C).

Definition 5—Two elements are *complementary* with each other if a change in one (resulting from a change in its relative price) is accompanied by a change in the other in the same direction. (This corresponds to definition 7 of Section I.)

As we have seen, this could happen only if the indirect price effect exceeds the direct price effect.

Definition 6—Whenever two elements are complementary with each other, the third variable element (or all the others taken together, if there are more than one) is *anticomplementary* with them. (The cross-elasticity is just as great for the third element as for the second, only in the other direction.)⁵ (This corresponds to definition 8 of Section I.)

Definition 7—Elements that are neither complementary nor anticomplementary with each other are *competitive* with each other. (This corresponds to definition 9 of Section I.)

Competitive elements may show positive or negative indirect price effects, but these are not strong enough in the positive direction to result in complementarity or strong enough in the negative direction to result in anticomplementarity.

We may now rewrite Theorem 1 more concisely as:

Theorem 1'—The elements in an economic situation cannot all be complementary with each other.

We can also see now that this is only a special case of a still more general theorem:

Theorem 1''—The indirect price effects (or the cross-elasticities of substitution or transformation) cannot be all positive or all negative.

This is because every indirect price effect that is positive for B , because it increases the ratio B/C , must be negative for C because it *ipso facto* reduces the ratio C/B .

All these relationships are most easily seen where the variable elements A , B , and C are all inputs. A fall in the relative price of A will result in more of A being used as it is substituted for the other variable inputs. There may be a

⁵ Note that although "indirect price effect" is different in Section II, "complementarity" and "anticomplementarity" have the same meaning as in Section I.

reduction in both B and C , in which case A is competitive with both of these. But it is also possible for one of them, say B , to be complementary with A . Although its price has not fallen, more of B is used because more of A is used. C will then have to decrease all the more, not only because A has been substituted for $(B + C)$ (in the direct price effect), but also to offset the still greater increase in B at the expense of C (in the indirect effect). This reflects C 's being anticomplementary with A . Since A must be complementary with B if B is complementary with A , C must be anticomplementary with B as well as with A .

The only remaining possibility is for A to be complementary with C and therefore anticomplementary with B , when B will have to be anticomplementary with C too. This is completely symmetrical with the case just considered and exhausts all the possibilities where the three variable elements are all inputs. In any triad, either all pairs are competitive or one pair is complementary and the other two pairs are anticomplementary.

The analysis is identical for the case where the variable elements are the outputs X , Y , Z , except that, unlike the inputs, these all have the same sign as elements. (We will now use the letters A , B , C , etc., only for inputs and the letters X , Y , Z , etc., only for outputs.) An increase in the price of an output X will result in more of it being produced. This may be accompanied by a decrease in all the other outputs Y and Z , in which case there is no complementarity or anticomplementarity in production. All the elements are competitive. On the other hand, one of the other outputs, say Y , may increase. In that case, we say that Y is complementary with X and we also have to say that Z is anticomplementary with X and that Z is anticomplementary with Y (since X is complementary with Y); and conversely, when Z is complementary with X , Y must be anticomplementary with X and with Z . As in the previous case, complementarity arises only if the cross-elasticity of substitution is sufficiently greater than the direct elasticity of substitution.

But this still does not exhaust all the cases covered by Theorem 1. What if one of the variable elements is an output and the other are inputs, output X and inputs A and B being the variable elements?

A decrease in the price of A will result in an increase in the input of A (a decrease in this element). This may result in the other elements all increasing. More of the cheapened input A (less of element A) works with less of input B (more of element B) producing more of output X (more of element X). There is no complementarity and no anticomplementarity, and all the elements are competitive with each other.

But it is also possible for one of the other elements to be complementary with A and to decrease when element A decreases. Suppose element B is complementary with A . Element B then decreases (input B increases). Element X will then have to be anticomplementary and increases all the more. We may then say, if we wish, that input B being complementary with input A , more of B has to be used together with the increased A , with a correspondingly large increase in output X . Here complementarity looks perfectly normal.

More interesting is the case where the element that is complementary with input A , is an output so that when input A increases (element A decreases),

output X (and element X) decreases. Here we have the case of regression [2, p. 93] where the cheapening of a factor of production and an increase in its use leads to a decrease in output! Regression is nothing but complementarity between an output and an input, but it does not look so normal.

We can handle this better by looking at a reduction in the output of X as the feeding of the lost output back into the process, treating it like an input and giving this imaginary input the name D ($\equiv -X$). Similarly we may treat a saving in the input of factor B as an increase in the output of the economized input item, giving this imaginary output the name W ($\equiv -B$). We now have complementarity of D with A . More of input D is used together with more of input A (both of these elements decreasing) in order to produce a large increase in W which is anticomplementary with A . Formally, this is just like the case above where there was also a large increase in output (there of X , here of W) even though this called for using more of another factor (there B , here D) and we have more of both factors producing more of the product. Re-translating this into our original letters, we can say that the complementarity of X with A means that a cheapening of A makes it worthwhile to forego some output of X in order to save on the input of B , since the release of large quantities of B reduces the output of X by very little (because B is anticomplementary with A and with X).

Still more interesting is the case (with the same variable elements A , B , and X) in which there is an increase in the relative price of X . The direct price effect is an increase in element X (and output X). If there is no complementarity, the other elements both diminish. This means that the inputs of A and B both increase and we have the familiar normal increase in production in response to an increase in the price of the product, by increasing all the factors of production.

But suppose element A is complementary with element X . Then the increase in X is accompanied by a movement of element A in the same direction. But an increase in element A is a decrease in input A ! This is the other side of regression. This may be dealt with analogously. Treat the saving of a unit of factor A as the production of a unit of an imaginary product called V ($\equiv -A$). Then complementarity of V with X means that as more of X is produced, it is worth devoting more of factor B to the production of V —i.e., to the economizing of A . But there is another and a more attractive way of dealing with this case: A is nothing but an inferior good in the production of X and B is therefore a superior good.

There remains only the case where there is one input and two outputs. But since we can freely translate outputs into inputs and vice versa, this is symmetrical if not identical with the case we have already considered.

What may seem surprising is how the concept of inferior goods crept into our discussion. Inferior and superior goods belong to the income effect which seems to have been left behind when we assumed the "other elements" fixed, concentrating on the direct and indirect price effects that comprise what Hicks called the substitution effect.

The answer seems to be that it depends on what are the other elements fixed. As long as all the outputs or products are fixed, we may say that real income

is fixed and we have only price effects and no income effects. Only inputs or factors of production are variable and we can speak only of complementary, competing, and anticomplementary inputs—the substance of Hicks' substitution effect. Similarly, if all the inputs or factors are fixed and only outputs or products are variable, we can speak only of complementarity, competition, and anticomplementarity in production.

But as soon as we permit some of the variable elements to be inputs and others to be outputs, the line between income effects and price effects becomes impossible to apply because holding the other elements constant no longer means the same as holding the level of real income constant. A rise in an output price relatively to an input price (which is the same as a fall in an input price relatively to an output price) induces an increase in input and in output and this is an increase in income; and conversely, a fall in output price relatively to input price induces a decrease in income.

Worse still, even in the case where the variable elements are all inputs or are all outputs, the line disappears as soon as we recognize that economizing a factor is equivalent to increasing a product, and increasing a product without decreasing any other product is clearly congruent with an income effect. Complementarity between an input and an output means that when the output is increased, the input is diminished, so that the input is inferior. When inputs in general are increased so as to produce more of the output, less is used of the inferior input. Complementarity between an input and an output also means that when the input is increased, the output is diminished so that the output is a regressive good. Just as complementarity turns out to include inferiority and regression, so anticomplementarity turns out to include superiority and progression (antiregression). We get inferiority or superiority if the output price changes relatively to the other prices, and regression or progression if it is the input price that changes relatively to the other prices. The inferiority, normality, and superiority of inputs and the regressivity, normality, and progressivity of outputs turn out to be only other sets of names for the three basic relationships between elements: complementarity, competitiveness, and anticomplementarity. Hicks' income effect turns out to be a special case of the indirect price effect, which in turn is a part of Hicks' substitution effect.

All these relationships are illustrated in Figure 2 where *A*, *B*, and *C* stand for inputs and *X*, *Y*, and *Z* stand for outputs. In the trios of capital letters forming the headings of the various columns, a line (marked *c*) connecting two letters, indicates that the two elements represented by the letters are complementary; and a small *a* between two letters indicates that the two elements are anticomplementary. The absence of such a line or letter indicates the absence of complementarity and of anticomplementarity so that the elements are competitive. The plus and minus signs represent increases or decreases in outputs or inputs resulting from the changes indicated at the left of the row, and for every plus there must be a corresponding minus. The signs would have to be reversed for inputs if we were to keep to the language of elements and that would make it easier to check on the symmetry and on the equality of plus and minus signs, but it seems to be easier to follow the meanings if we keep to the

CASE I

FIGURE 2

English usage. The number of plus or minus signs indicate the number of influences that would cause the element to vary in the direction indicated. They must not be understood to indicate the *size* of a change because a single influence in one instance might be quantitatively greater than as many as four influences in another instance. It must also be remembered that the anticomplementarity the third element with the two complementary elements refers only to all the other elements (other, that is, than the complementary pair) *taken as a whole* if there are more than one of them. Any proper subset of these may be competitive or even complementary with the complementary pair.

In Case I of Figure 2, the three variable elements are all inputs. (If there are more than three, all those left after two have been considered may be treated as the third element.) The first column shows three competitive inputs. There are two plus signs attached to the *A* in the first row of the first column to indicate that *A* is substituted for *B* as well as for *C*. The minus signs attached to the *B* and the *C* show the other side of the same substitution. The number of plus signs in each case must therefore be equal to the number of minus signs. The same relationship is seen in the next two rows in this column.

The second column in Case I shows *A* and *B* complementary so that *A* and

C are anticomplementary as also are B and C . The first row here differs from the first row in the first column because the complementarity between A and B means that there is an indirect price effect causing B to be substituted for C to such a degree that the $B-$ is turned into a $B+$. This is balanced by the two additional minus signs attached to the C , one to balance the removal of the original minus attached to the B and another to balance the plus put in its place. As before, the total number of plus signs is equal to the total number of minus signs. The second row shows the same thing for a cheapening of B instead of a cheapening of A . The third row is different because it is now not one of the complementary inputs that is cheapened, but the one that is anticomplementary with the other two. The cheapening of C causes C to be substituted for both A and B . But the complementarity causes A to be reduced further because there is less of its complement B , and it causes B to be reduced further because there is less of its complement A . A and B therefore given an additional minus each and two more plus signs are added to C as more of it has to be added to compensate for both of these further contractions if output (and any other elements) are to be held constant. The next two columns of Case I follow exactly the same principles.

Case II shows the completely symmetrical relationships for three variable outputs X , Y , and Z , Case III shows two variable inputs A and B , and one variable output X , and Case IV shows one variable input A and two variable outputs X and Y . An inferior input is indicated by i , a superior input by s , a regressive output by r , a progressive output by p . (These subscripts are put in parentheses where inputs are treated as outputs or outputs as inputs.)

The blurring of the line between income effects and price effects is a result of an ambiguity of the word "income" that is inevitable as soon as it is applied to more than one homogeneous item. In the analysis of income, this is avoided by treating the utility produced by the consumption goods (plus or including saving), or the level of income, as such a single homogeneous item. In the analysis of production on the same line as consumption, it seems natural to consider the restriction imposed by a constancy of the "other elements," when some are varied in response to changes in relative price, as corresponding to the restriction imposed by a constancy of the level of income. This is most natural when the "other elements" which are kept constant consist of all the outputs or products. The analogy still seems to make some kind of sense, as indicating a given level, where the constant "other elements" consists of all the inputs. The analogy is clearly invalid where the varied elements include an input and an output because that permits production and consumption to increase or decrease, but it is only the *visibility* of the invalidity that is affected. The same trouble exists even when the variable elements are all inputs or all outputs. The increase in one output at the expense of a decrease in another output is no different from an increase in an output at the expense of an increase in an input; and a decrease in one input at the cost of increasing another input is no different from a decrease in an input at the cost of decreasing an output. They are just like an increase or a decrease in production.

One is tempted to avoid these embarrassments by simply defining an in-

crease in an output as an increase in output-income, and an increase in an input as an increase in input-income. It is in relation to increases in output-income that an input may be inferior or superior, and it is in relation to an increase in input-income that an output may be regressive or progressive.

Our framework, however, still prevents a "Giffen case" from appearing. A "Giffen case" means an increase in an output when its price falls (or an increase in an input when its price rises); i.e., an element moving in the opposite direction to the change in its price. This can occur only if something other than the change in relative prices permits an increase in the element which more than offsets the direct price effect which, according to Theorem 3, is always positive, i.e., in the same direction as the price change. That something must mean not merely an increase in output-income or in input-income but an increase in income in the general and original sense of an increase in all the elements or an increase in some elements without any elements decreasing, and that is ruled out by Theorem I. Since an input is a negative element, income, or the sum of *all* the elements, consists of output-income minus input-income. Our elimination of income changes in this general sense does not prevent the emergence of inferiority, superiority, progression and regression as aspects of complementarity and anticomplementarity, but it does prevent the emergence of a Giffen effect.

MATHEMATICAL APPENDIX

Let us consider a general case of n commodities, labeled $1, \dots, n$. Quantities of n commodities to be produced or to be consumed are presented by vectors with n components; thus $x = (x_1, \dots, x_n)$ stands for a situation at which each commodity i is produced by the amount x_i or consumed by the amount $-x_i$ ($i = 1, \dots, n$). An opportunity set T consists of all commodity bundles which may be conceivably chosen. In production theory, it comprises all input-output combinations which are feasible under given technological conditions, while in consumption theory, it consists of all commodity bundles which give at least as much utility as a given level of utility.

If $p = (p_1, \dots, p_n)$ stands for a price vector, of which the i th component represents the price of the i -th commodity, then what Lerner calls an economic situation corresponds to choosing a commodity bundle (x_1, \dots, x_n) for which the (net) revenue $\sum_{i=1}^n p_i x_i$ is maximized in the opportunity

set T . The optimum commodity bundle associated with price vector $p = (p_1, \dots, p_n)$ will be denoted by $(x_1(p), \dots, x_n(p))$; formally,

$$(1) \quad (x_1(p), \dots, x_n(p)) \in T,$$

and

$$(2) \quad \sum_{i=1}^n p_i x_i(p) \geq \sum_{i=1}^n p_i x_i, \text{ for all commodity bundles } (x_1, \dots, x_n) \text{ in } T.$$

The maximized revenue, which depends on prices (p_1, \dots, p_n) , is denoted by $r(p)$:

$$(3) \quad r(p) = \sum_{i=1}^n p_i x_i(p).$$

It is postulated that the optimum commodity bundle $x(p) = (x_1(p), \dots, x_n(p))$ uniquely exists for any positive price vector $p = (p_1, \dots, p_n)$, and that $x_i(p)$ are continuously differentiable.

The hypotheses postulated above imply all the fundamental properties concerning the rates of changes in optimum commodity bundles with respect to price changes. The derivation presented here is based on Lionel W. McKenzie's method, as introduced in his article "Demand Theory without a Utility Index," *Review of Economic Studies* (1956-57), 24, 185-89.

Let the prices be changed from (p_1, \dots, p_n) to $(p_1 + \Delta p_1, \dots, p_n + \Delta p_n)$ and correspondingly the optimum commodity bundle be changed from (x_1, \dots, x_n) to $(x_1 + \Delta x_1, \dots, x_n + \Delta x_n)$. Since the commodity bundle (x_1, \dots, x_n) is optimum when prices are (p_1, \dots, p_n) , the revenue evaluated at prices (p_1, \dots, p_n) is greater at (x_1, \dots, x_n) than at any other commodity bundles in the opportunity set T . In particular,

$$\sum_{i=1}^n p_i x_i \geq \sum_{i=1}^n p_i (x_i + \Delta x_i),$$

hence,

$$(4) \quad \sum_{i=1}^n p_i \Delta x_i \leq 0.$$

Similarly, since $(x_1 + \Delta x_1, \dots, x_n + \Delta x_n)$ is optimum with respect to $(p_1 + \Delta p_1, \dots, p_n + \Delta p_n)$,

$$(5) \quad \sum_{i=1}^n (p_i + \Delta p_i)(-\Delta x_i) \leq 0.$$

Adding (5) to (4), we have

$$(6) \quad \sum_{i=1}^n \Delta p_i \Delta x_i \geq 0.$$

It is first observed that

$$(7) \quad \sum_{i=1}^n p_i \frac{\partial x_i}{\partial p_j} = 0, \quad j = 1, \dots, n;$$

namely, the effects of a change in the price of a commodity on the optimum quantities cancel out if they are weighted by respective prices. It may be noted that the cross derivatives $-\partial x_i/\partial p_j$ are exactly equal to Slutsky's substitution terms in consumption theory.

To see (7), let us consider a change in prices for which

$$\Delta p_1 = 0, \dots, \Delta p_j > 0, \dots, \Delta p_n = 0.$$

Divide (4) and (5) by Δp_j and let Δp_j tend to zero, then we have (7).

The relation (7) may be used to derive the following identity:

$$(8) \quad \frac{\partial r}{\partial p_j} = x_j(p), \quad j = 1, \dots, n,$$

where $r=r(p)$ the revenue function defined by (3). Indeed, differentiate (3) partially with respect to p_j to get

$$\frac{\partial r}{\partial p_j} = \sum_{i=1}^n p_i \frac{\partial x_i}{\partial p_j} + x_j(p),$$

which, due to (7), implies (8).

Differentiating (8) with respect to p_k and making use of Young's theorem, we have the proposition that the price effects are symmetric:

$$(9) \quad \frac{\partial x_j}{\partial p_k} = \frac{\partial x_k}{\partial p_j}, \quad \text{for all } j, k = 1, \dots, n.$$

It is also shown that the price effects $\partial x_j/\partial p_k$ are positive semidefinite; namely,

$$(10) \quad \sum_{j,k=1}^n \frac{\partial x_j}{\partial p_k} v_j v_k \geq 0, \quad \text{for all } v = (v_1, \dots, v_n).$$

The validity of the relation (10) may be indicated by (6). It is formally shown as follows: Define the function $\varphi(t)$ by

$$(11) \quad \varphi(t) = \sum_{i=1}^n p_i x_i(p + tv) - \sum_{i=1}^n p_i x_i(p).$$

We have from (2) that

$$\varphi(t) \leq \varphi(0) = 0, \quad \text{for all } t \geq 0.$$

Differentiating $\varphi(t)$ with respect to t , we get:

$$\varphi'(t) = \sum_{i,j=1}^n p_i \frac{\partial x_i(p + tv)}{\partial p_j} v_j;$$

but, from (7),

$$\sum_{i=1}^n (p_i + tv_i) \frac{\partial x_i(p + tv)}{\partial p_j} = 0.$$

Hence

$$(12) \quad \varphi'(t) = -t \sum_{i,j=1}^n \frac{\partial x_i(p + tv)}{\partial p_j} v_i v_j, \quad \text{for all } t \geq 0.$$

On the other hand, we have from (11) that

$$(13) \quad \varphi'(0) \leq 0.$$

The relations (12) and (13) together imply the inequality (10).

The inequality (10) in particular implies that

$$(14) \quad \frac{\partial x_i}{\partial p_i} \geq 0, \quad i = 1, \dots, n;$$

namely, the own price effect is positive (or possibly zero).

The relation (7) combined with (9) yields Euler's identity:

$$(15) \quad \sum_{i=1}^n p_i \frac{\partial x_j}{\partial p_i} = 0, \quad j = 1, \dots, n,$$

which may be directly derived from the zero-th homogeneity of the functions $x_1(p), \dots, x_n(p)$.

It is easily seen that Lerner's Theorems 1-5 in Section II are simple consequences of (7), (14), and (15) above.

Definition: Commodity j is complementary with commodity i , if

$$(16) \quad \frac{\partial x_j}{\partial p_i} \geq 0;$$

commodity j is anticomplementary with a commodity i , if

$$(17) \quad \frac{\partial x_j}{\partial p_i} < 0, \quad \frac{\partial \left(\sum_{k \neq i,j} p_k x_k \right)}{\partial p_i} > 0;$$

and commodity j is competitive with commodity i , if

$$(18) \quad \frac{\partial x_j}{\partial p_i} < 0, \quad \frac{\partial \left(\sum_{k \neq i,j} p_k x_k \right)}{\partial p_i} \leq 0.$$

From the definition, any commodity j is either complementary, anti-complementary, or competitive with any other commodity i . The symmetry (9) implies that if commodity j is complementary with commodity i , then commodity i is complementary with j , and vice versa. In the case which involves only three commodities, it is seen from the definition that i and j are complementary if and only if i is anticomplementary with k ; hence, if i is anticomplementary with k then k is anticomplementary with i . In the general case in which the number of commodities is greater than three, however, it may be the case that commodity j is anticomplementary (or competitive) with commodity i , but commodity i is competitive (or anti-complementary) with commodity j .

In view of (7) and (14), if commodity j is complementary with commodity i , then

$$(19) \quad \frac{\partial \left(\sum_{k \neq i, j} p_k x_k \right)}{\partial p_i} \leq 0.$$

Finally, Lerner's direct and indirect price effects may be stated in our terminology by the following:

Definition: The price effect P_{ij} of i with respect to j is defined by

$$(20) \quad P_{ij} = \frac{\partial \left(x_i / \sum_{k \neq i} p_k x_k \right)}{\partial p_j},$$

where i and j may be an identical commodity.

The Effect of Integration on Property Values

The purpose of this paper is to explore the reaction of neighborhood housing prices to racial integration. What happens to property values when one or more Negro families move into a previously all-white neighborhood? The answer arrived at in the analysis to follow is based on a study in Ann Arbor, Michigan.

The data are analyzed in two different ways. First, an analysis is carried out on houses that sold at least two times—once before and once after neighborhood integration. For purposes of comparison, data on similarly-priced houses in all-white areas are also included. However, it may be that integration affects property values some years after the first Negro family moves into the neighborhood. Houses which sold twice at least five years subsequent to Negro entry are studied in an attempt to investigate any longer-run effect of integration on property values.

The second method uses assessed valuations of properties. Comparisons are

made over time on the basis of a ratio of market to assessed value for different neighborhoods and for different sections within a neighborhood. The trends established by these ratios over a number of years are examined to see if property values do react to integration and if so in what way. The use of assessed values for this purpose is supported by a regression analysis.

Both methods of analyzing the data point to the conclusion that racial integration does not affect property values.

The approach used here is an alternative to the "control area" technique used by Laurenti [1] and in the Kalamazoo study [2]. In their approach, areas of recent integration are compared to all-white areas which match (as nearly as possible) the integrated areas in all essential characteristics except Negro occupancy. However, because of the many dimensions in which neighborhoods vary, good control areas are difficult to find. Factors such as services available, type of nearby construction, zoning ordinances, and accessibility to schools and business districts are just a few of the elements whose variation can alter the comparability of neighborhoods.

Although differing in method our analysis supports the findings of these earlier studies. Laurenti's basic conclusion is that integration is not associated with any single pattern in housing prices. However, he finds that integration is more often associated with stability or price improvement than it is with price softening [1, pp. 5-49]. Although the Kalamazoo study was primarily addressed to sociological questions, some price evidence is given. The major finding, for this part of the study, is that market values are not affected by integration [2, pp. 20-25].

I. *First Method*

The starting point in this analysis is a comparison of the values of five houses which sold twice—once before and once after area integration. Data from two integrated neighborhoods covering the period between January 1950 and December 1960 are used.¹ Integration occurred in 1955 in area A and 1958 in area B. By 1960 only one Negro family had purchased a home in each of these areas. Both neighborhoods consist of houses facing short residential streets. There are 35 such houses in area A and 20 in area B. The houses range in price from \$13,000 to \$31,500 in area A and \$10,000 to \$17,500 in area B.² Most of the homes have five rooms and were built in the early 1950's. Table 1 shows that the market value for each of the houses was higher after than before integration. The average increase in actual prices is substantial. However, when the inflation that occurred in construction costs is allowed for,³ only a slight average increase primarily due to the influence of one house is apparent.

¹ Some of this statistical information as well as that presented later was secured from personal interviews and from the records of real estate brokers. Most of the data, however, was obtained from the City Assessor's Office. A considerable amount of the price information was computed from the face value of the federal tax stamps affixed to property deeds. This is a simple procedure because the tax is paid at a rate of \$1.10 per \$1,000 of purchase price.

² The figures show the range in market value for all the transactions recorded for each neighborhood. All of this data is used in the analysis in the second section of the paper.

³ Only prices relevant to the residential housing industry in this part of Michigan are

TABLE 1—PRICES OF HOUSES IN INTEGRATED AREAS SELLING BETWEEN 1950 AND 1960:
HOUSES WHICH SOLD BOTH BEFORE AND AFTER INTEGRATION
(Area A integrated in 1955 and Area B in 1958)

Houses	Years Sold	Actual Market Value			Deflated Market Value (1960 \$)		
		Before	After	Difference	Before	After	Difference
#1-A	1955, '58	\$26,500	\$31,500	+\$5,000	\$30,377	\$33,248	+\$2,871
#2-B	1954, '59	13,500	14,500	+ 1,000	15,475	14,802	— 673
#3-B	1955, '60	10,000	12,000	+ 2,000	11,460	12,064	+ 604
#4-B	1955, '59	13,000	14,500	+ 1,500	15,466	14,802	— 664
#5-B	1954, '59	12,000	13,400 ^a	+ 1,400	14,450	13,574	— 876
Average values		15,000	17,180		17,446	17,698	
Average differences				+ 2,180			+ 252
Standard error of average differences (1 sigma)				(690)			(610)

^a This is an adjusted figure. It takes account of an improvement made to the property during the time interval between sales.

The observed increase in actual prices is fairly well accounted for by the rise in construction costs. In constant dollars (1960 = 1.00) the average price increase from first to second sale is not statistically significant.

The sales prices of houses in all-white neighborhoods that sold twice between January 1950 and December 1960 are now considered. The houses in the all-white areas satisfy three requirements: First, the initial sales prices of these houses are within the price range of corresponding sales in the two integrated areas. Second, the houses sold twice during the same time-period in which houses in the integrated areas sold. Finally, the assessed value of each house was not changed during the time interval between first and second sale. Table 2 shows price data obtained from all-white areas. The findings are quite similar to those in Table 1. Ten of the twelve houses increased in value from first to second sale. The increase in average price in the all-white area is not as large as in the integrated area, but the standard errors show that the observed differences in real market value between the two cases are not significant at the 5 per cent level.⁴

The final comparison in this part of the study involves houses which sold subsequently to area integration. Area C was integrated in 1945 and as of 1960 about 30 per cent of the occupants were Negro. Some of the houses in this area sold at least twice between 1950 and 1960. An investigation of the price behavior of these houses should reflect any longer-run effect of integration.⁵

used in the price index. These "Comparative Cost Multipliers" were obtained from the Assessor's Office. For the relevant years they are:

1950 = 1.3595	1953 = 1.2295	1956 = 1.0995	1959 = 1.0193
1951 = 1.2783	1954 = 1.2045	1957 = 1.0678	1960 = 1.0000
1952 = 1.2568	1955 = 1.1463	1958 = 1.0523	

⁴ The standard error of the difference between mean differences is 1.06 sigmas.

⁵ The assessor's records only go back to 1944; otherwise it might have been possible to obtain useful preintegration price data on these houses.

Average Differences				+ 1,706			+ 176
Standard Error of Average Differences (1 sigma)				(350)			(400)

Area C is much larger and more heterogeneous than the other integrated areas. It consists of about 700 homes, some built prior to the 1860's, others in the early 1950's, with substantial variation in both number of rooms and market value. Sizes range from 4 to 12 rooms and market value from \$6,000 to \$35,000. Table 3 shows the data on postintegration sales. With one exception, all of the houses increased in actual market value from first to second sale. On the whole the results are very similar to those obtained from the two previous comparisons.

The findings for this part of the study are contrary to the belief sometimes heard that integration depresses property values. The similarity in price behavior of the three cases studied suggests that integration does not affect neighborhood property values.

II. *Second Method*

In this part of the analysis, the behavior of housing prices is expressed in terms of a ratio of market to assessed value.⁶

Two questions concerning the adequacy of assessed values must first be answered. The first question is: Are houses in different neighborhoods assessed at about the same rate? The data in Table 4 suggest that they are. Although

TABLE 4—HOUSING DATA FOR THREE AREAS

Description	Area A	Area B	Area C
Average market value (1960 dollars)	\$22,160	\$13,940	\$16,814
Average assessment (dollars)	5,280	3,472	3,851
Average ratio:assessment to price	.238	.249	.230
Number of sales	22	23	135

differing substantially in average price, the neighborhoods (A, B, C) are quite comparable in terms of the ratio of assessed value to market value. In this respect, two of the areas differ by less than 1 per cent and the total variation is only 1.9 per cent.

The second question is: Are houses in different price ranges assessed at about the same rate? A regression analysis was carried out to provide an answer to this question. Treating each area separately, the data points used to determine the regression equation were obtained by averaging all transactions and their associated assessed values for all houses which sold in the same year.⁷

⁶ Assessments in Ann Arbor are based on "real" cost. Using 1941 price levels, the assessor attempts to compute the replacement cost of properties. Usually, each property is assessed only one time. If improvements to a property are recorded, the assessed-value figure is adjusted accordingly.

⁷ There are no sales recorded for some years within the time period covered by this study. The number of average yearly transactions recorded for each area is as follows: Area A: 7; Area B: 6; Area C: 11. The closeness of fit observed in the regression arises from the fact that averages rather than data on individual sales are used in this analysis.

FIGURE 1. THE RELATIONSHIP OF ASSESSED VALUE (A.V.) TO MARKET VALUE (M.V.)

FIGURE 2. TREND OF AVERAGE PRICE TO AVERAGE ASSESSED VALUE

TABLE 5—HOUSING DATA TABULATION ON THE BASIS OF NEGRO OCCUPANCY

	Area C		
	Sections Having No Negro Occupants	Sections Where Negroes are a Majority	All Other Sections (Sections Having about 20 Per Cent Negro Occupants)
Average market value (1960 dollars)	\$23,343	\$13,794	\$14,480
Average assessment (\$)	5,506	3,015	3,383
Average ratio:assessment to price	.235	.219	.233
Number of sales	31	44	60

The regression line and its scatter are shown in Figure 1. The regression equation is:

$$M.V. = -.079 + 4.31A.V. \\ (.26)$$

This relationship is a highly significant one and over 85 per cent of the variation in real market value is associated with quality of house as measured by assessed value.⁸ As is apparent in Figure 1, there is no substantial curvature embodied in the relationship: no bias in assessments according to price class is apparent. The use of assessed values as a control for quality of house appears justified.

Let us now see how market values in the three areas vary over time. Figure 2 illustrates the similarity of the three areas with respect to price behavior. A slight decline, common to each area, is observed. In the year following integration (1955 for area A and 1958 for area B), prices improved. The general impression, however, seems to be one of stability; that is, the trend in actual market value parallels, quite closely, the trend in construction costs over the relevant time period. This finding is identical to the one found earlier in the paper by a different method. Surely the presence or absence of Negroes is not reflected by the price data.

One may still wonder if any price differential can be observed between market values in all-white sections close to Negro occupants and market values in the integrated sections. Area C is a neighborhood that permits such a comparison. Within area C, some parts are predominantly Negro and other are all-white. A classification was made, selecting those sections having at least a 50 per cent Negro population for comparison with those parts having no Negro population. This information is summarized in Table 5. There is a large difference between these sections with respect to average market value, but in the case of the ratios of assessed value to market value there is only a small

⁸ $F = 267$; $F.01 = 7.95$; $R^2 = .87$.

difference—1.6 per cent. If anything, prices are higher relative to assessed values in the sections that have the highest percentage of Negro occupants.

BOOK REVIEWS

General Economics; Methodology

Economic Performance—An Introduction to Economics. By H. H. VILLARD.
New York: Holt, Rinehart and Winston, 1961. Pp. xiii, 655. \$6.50.

Professor Villard introduces the student to economics in an unconventional way by concentrating on the short-run and long-run factors that influence the economic performance of our economy. He examines the roles of the economizing process, economic development, and income stabilization in determining the performance of the economy, and concludes that faster economic development or growth would make the most contribution to an improvement in performance.

On the whole, Villard presents a persuasive case for the paramount significance of rapid economic development as a measure of and means to superior performance in our economy. The marked difference in improvement of economic well-being that results from fast rather than from slow rates of economic growth is dramatized in his analysis. Thus over a ten-year period, a 3 per cent productivity factor provides a 16 per cent greater increase in output than a 1.5 per cent factor, while a 4.5 per cent productivity factor provides a 34 per cent greater increase in output than a 1.5 per cent factor. He also derives imaginative data which suggest that over a ten-year period, increases in output due to productivity gains will tend to overshadow the improvement in economic performance that is possible from the elimination of the wastes of advertising, monopoly, labor unions, tariffs, agriculture, restrictive price competition, consumer ignorance, and unemployment. And Villard demonstrates further that an increase of 3 per cent in the annual productivity factor would contribute vastly more to an improved economic performance over an extended period of 25 years than would the realization of the most efficient economizing processes.

Although Villard develops a convincing argument for the importance of faster economic growth, his treatment of several other facets of economic performance leaves me with some misgivings. My concern is not with centering the study of economics around economic performance, for this seems to me to be a very promising approach. Rather I am troubled by his inadequate discussion of the basic tools of analysis which he and most economists agree are necessary for an understanding of economic problems. In part my criticism stems from the organization of the book, for Villard interrupts the continuity of discussion in the early chapters by referring on numerous occasions to figures, tables, and data that are to be found in other chapters. More important, however, the sections on demand and supply tools of analysis and on money and banking lack clarity, and contain inaccuracies as well. The treatment of programs to aid agriculture, for example (pp. 296-97), provides an especially glaring instance of an error in analysis. For the agricultural surplus described

here results only if the supply curve is perfectly inelastic and not as it is depicted in Figure 25-1. With the given long-run supply curve shown in the figure, the amount supplied at the high price op' would greatly exceed the $a'a$ stated in the text. And in analyzing Situation 13 (pp. 544-45) he overlooks the important point that the individual bank itself has contributed to credit creation because the money supply is larger by the \$8 of currency withdrawn into general circulation and later deposited in other banks.

Elementary students will also have difficulty in following Villard's analysis at several other points because he presents insufficient detail in developing a number of analytical concepts. Thus although he minimizes the use of marginal analysis in the elementary course—and rightly so in my judgment—too little attention is given to presenting the meaning of the marginal analysis in some of the instances in which it is employed (pp. 171-72). Other concepts that should be clarified include his statements on elasticity and marginal revenue (p. 91); on the short-run supply curve (p. 129); on bank credit creation (pp. 532, 545); and on the multiplier (pp. 584-88).

The chapter on natural monopolies deserves commendation for its very clear discussion of the costs and problems involved in government ownership or regulation of natural monopolies. Of special interest also is Villard's demonstration in another chapter that there would be surprisingly little improvement in the economic welfare of the average income recipient if all upper incomes were reduced to $2\frac{1}{2}$ times the national average.

The strongest points of the book are the detailing of the many perplexing problems that are associated with accelerating economic development and the discussion of the improvement in economic performance that would result from faster economic growth and from the elimination of economic waste. The book must be found wanting, however, as an elementary introduction to the economizing process.

KENNETH D. ROOSE

Michigan State University, Oakland

Economics. By ABRAHAM L. GITLOW. New York: Oxford University Press, 1962. Pp. xxii, 743. \$7.50. Accompanying workbook.

The latest entry into the overcrowded Principles market follows the established pattern of minimum differentiation. The topics covered, the organization, and the mix of theory, institutional material, and policy are about what one would expect; however, there are a few surprises.

There is an excellent chapter on the neglected topic of conservation, with special emphasis on minerals, farmland, water, and forests. And there is an extended review of the various ways society has sought to protect people from the hazards of modern industrialism through such means as social security, unemployment compensation, workmen's compensation, private life insurance, and pension plans. Finally, the lively and enthusiastic presentation, replete with adages and admonitions that an important point has just been made, is frequently punctuated with long quotations from other writers, quotations which sometimes serve to carry the burden of the discussion; on the whole the technique is successful.

The theme of the book, Mr. Galbraith notwithstanding, is scarcity and choice, and the crucial issue of our time, as stated in the Preface, is whether society should rely on the free market or central planning in making its decisions; and one's choice, Gitlow argues, depends on whether primacy is given to individual freedom and individual want satisfaction or social goals. In the end, Gitlow takes his stand in favor of the free consumer but concedes that the choice is not either/or but rather one of degree; thus the crucial problem facing the members of society is one of choosing "the mix of free market and central economic direction truly consistent with their goals of individual freedom and social welfare. May they avoid pursuing the one so far that they lose the other" (p. 721).

The presentation is somewhat uneven in quality. Generally speaking, Gitlow is quite effective in microanalysis and in the descriptive sections. The chapters on demand, cost, competitive pricing, marginal productivity, and wage theory are models of care, clarity, and rigor, and the accompanying tables and graphs are as well done as any I have seen. Many will also appreciate the factor of production approach to the growth process. Gitlow's discussion of price indexes, labor force data, conservation, organized labor, income distribution, and social security represents descriptive economics at its best. The only exceptions to the strong showing of the microeconomic and descriptive chapters occur in the chapters on agriculture, oligopoly, and antitrust. Although the chapter on agriculture contains some interesting statistics, the discussion is so burdened with facts that the analysis and the policy alternatives seem to get lost. Oligopoly pricing is polished off in three paragraphs and antitrust emerges as a string of cases, amorphous and inane. To what extent this less satisfactory showing in these areas is due to the state of economics, I leave to the reader.

The macroeconomic analysis is less imposing. Chapter 2, ostensibly an introductory chapter on money, offers the student a potpourri of topics including, *inter alia*, hoarding and dishoarding, government borrowing, and the relationship of money to the price level; such delicate topics could be handled more intelligibly and with more finesse at a later stage in the theoretical development. Business cycles are treated descriptively, in the tradition of Mitchell, without the benefit of theory. And income determination is not clearly presented: for example, under the topic heading, "Fluctuations in National Income and Employment," Gitlow attempts to explain the equilibrium level of income in terms of the relationship between current and planned investment (pp. 151-53). There is no explanation of how the two can differ, and no explanation of how this relationship is connected, if at all, with the saving and investment relationship; it will not be surprising if the student finds this tough going.

There are a few minor annoyances. An inelastic demand is listed as one of the six conditions necessary for absolute monopoly (p. 409). Some will certainly question the implication of the statement that Burns and Mitchell demonstrated "some tendency for two or three minor cycles to occur within each major cycle" (p. 126). Finally, it is unfortunate that in discussing the Clayton Act Gitlow presents the unamended provisions governing price discrimination and mergers (p. 448).

The weight of my criticisms should not be exaggerated. Generally, the technical analysis is competent, demanding but not overly rigorous. The institutional topics are succinctly stated and the statistics are up-to-date and skillfully integrated with the discussion. While Gitlow's policy preferences are quite clear, he does not force his opinions on the reader. Thus I would judge the book to be generally satisfactory and a valuable teaching aid.

BRYCE J. JONES

*St. Joseph's College
Rensselaer, Indiana*

Schein und Wirklichkeit in der Volkswirtschaft. By ADOLF WEBER. Berlin: Duncker & Humblot, 1961. Pp. 449. DM 33.60.

Adolf Weber, an octogenarian now, devotes this new volume to a restatement of the views he has expounded as a venerated teacher for sixty years. Their essence is conveyed by the first sentence of the preface in these words: "It is not difficult, with the help of the printing press and of deposit currency, to conjure up a deceptive flowering of the economy which at first is hardly distinguishable from lasting and genuine economic success." The key words in the title of the book—"appearance" and "reality"—allude to this alleged contrast between the deceptive vistas of wishful thinking and the hard though hidden truth.

The 15 chapters of this volume, largely composed of quotations from earlier writings, are essentially variations on the same theme of a threatening worldwide capital shortage veiled by inflationary boom. As a straight restatement of Weber's well-known and rather dogmatic views, the book seems mainly to be intended to demonstrate the author's sagacity and clairvoyance through his own factual interpretation as well as through the favorable testimony of others. It is probably not personal vanity but rather his deep concern about prevailing economic trends which has prompted Weber to stake out once more, and almost in the form of a testament, his claims to the role of a not sufficiently recognized defender of an equally insufficiently recognized truth.

The first and last chapter concentrate on the highly personal aspects of Weber's economic philosophy under the heading of "Economics and 'Weltanschauung'," and of his professional development in comments on "The Author and His Field of Study." The first two of the intervening 13 chapters, tracing the relationship between "Market Orientation and the National Economic Order" and between "Money and Capital," provide the analytical pattern whose implications are projected on major aspects of economic policy in the remaining chapters.

Weber's economic creed, as he himself admits, is entirely eclectic. Its basis is an intimate fusion of two so heterogeneous beliefs as those in the benevolent rule of the free market and in the necessity of governmental interference with that rule in the social interest. He stands strictly behind Adam Smith whose views he modernizes with von Thuenen's and Clark's contributions to marginal productivity theory and with the Wicksellian concept of the "natural" rate of interest; he is critical of Ricardo, opposes German historicism as well as Austrian subjectivism, and despises Keynesism. Implicitly he denies the validity of

theoretical welfare economics when he strongly asserts that our economic problems can be solved only if we "put next to our theoretical knowledge . . . the belief in a supra-natural being beyond the individual and the state" since only such a belief can create the sense of duty needed for the proper recognition of the social interest.

It is obvious that the guidance which Weber himself receives from his strong religious conscience is not very useful as a general criterion for what is, or is not, socially desirable; as a consequence, he may be readily criticized for drawing the limits of desirable governmental action too narrowly or unnecessarily wide. And it does not seem that this lack of a valid line of demarcation is sufficiently remedied by resolving doubts in favor of a standard which elevates long-range capital formation to the foremost goal. This, after all, is the essence of the present economic philosophy of the Soviets whose harsh incidence on consumers' welfare is so strongly criticized in the West. The practical failure of this method becomes apparent when Weber, carried by the combination of his high-minded social responsibility and his extreme fear of capital shortage, defines the "just wage" as "the highest possible wage reconcilable with the *lasting* increase of labor's real wage" (*italics in the text*), which, in a capital-poor country, would justify any existing wage level.

Weber's hybrid economic philosophy operates almost exclusively with the analytical tool into which he fashions the concept of capital shortage. He reasons that our understanding of this phenomenon is fundamentally marred by not distinguishing properly between the concepts of "money" and "capital"; that only genuine savings represent capital and that the increase in the money supply which typically accompanies the issuance of deposit currency leads either to open or hidden inflation; that inflation of either type unduly enhances spending and starves capital formation; and that these trends, now almost universal in the world, must soon lead to a day of reckoning. Weber insists that these views, expounded with obviously no major changes for 60 years, have stood the test of the times and are bound to assert their correctness in the years ahead; but in view of the scepticism with which the capital-shortage theory is regarded in general, his present documentation will hardly convince anyone who has not been convinced before, even if he has his own doubts about the uninterrupted continuance of present prosperity trends.

In practical application, Weber's fundamental analysis has prompted him to react to the Marshall Plan with the fear that "the flooding of West Europe with American money would tend to delay rather than to speed up the natural process of equalization which only could be accomplished by the elimination of protectionism" (p. 124), although he had insisted in 1946 that "without outside help the re-establishment of our economy is unthinkable" (p. 185); to charge the occupation regime for a good deal of the difficulties which German postwar recovery had to overcome since it "attempted to continue the most primitive forms of the national-socialistic price policy" (p. 274); to insist that in view of the increasing capital shortage "we do not only live beyond our means but also carry the processes of technological improvement and of building beyond this limit" (p. 196); to argue that attempts of the United States to increase Germany's burdens in order to relieve its own balance-of-payments

difficulties would render Germany's capital problem so grave as to invite her early economic disaster and that of the free world; and finally to deprecate the German *Wirtschaftswunder* with the argument that the admittedly great progress is largely an inflationary mirage rather than firmly established success.

Limitations of space do not permit presentation of a representative sample of the many statements of fact that could hardly stand careful scrutiny, and those referring to conditions in the United States would have to be put close to the top of such a list. It is also doubtful that his methodological assault on the validity of functional thinking in economics and his plea for a return to old-fashioned causal concepts will find much approval.

In spite of all these shortcomings, there remains, however, a definite contribution which Adolf Weber's economic philosophy and its dissemination by the spoken and written word over so many decades have meant for the teaching of economics in Germany as well as for German economic policy. It has, perhaps decisively, steered German thinking away from the limitations of all-too-rampant historicism and has favored the acceptance of the classical precepts which, no doubt, had an important role to play in the re-building of a devastated country. And since the man who is generally credited with having engineered the "German economic miracle," Ludwig Erhart, has been a member of Weber's circle, this influence may have been even greater than it appears on the record.

Price and Allocation Theory: Income and Employment Theory; Related Empirical Studies; History of Economic Thought

Capital in the American Economy, Its Formation and Financing. By SIMON KUZNETS. Princeton: Princeton University Press, for National Bureau of Economic Research, 1961. Pp. xxix, 664. \$12.00.

This long-awaited volume completes the massive NBER study of capital formation and financing in the American economy. Professor Kuznets pulls together the findings of his associates, contained in the six sector studies issued earlier,¹ examines them in the light of his own estimates of country-wide capital formation, and provides an extended commentary and interpretation of the findings. This series of volumes, and particularly Kuznets' capstone volume, have already become a *sine qua non* to those engaged in analyzing the past, present, and potential future growth of the American economy. For the voluminous data on the magnitude, distribution, and financing of capital formation, the profession will long be in debt to Kuznets and his colleagues. On the other hand, a very large number in the profession will, I suspect, take vigorous issue

¹The prior six volumes, all published by Princeton University Press for the National Bureau of Economic Research, are: *Capital Formation in Residential Real Estate: Trends and Prospects*, by Leo Goebler, D. M. Blank, and Louis Winnick (1956); *Capital in Agriculture: Its Formation and Financing since 1870*, by A. S. Tostlebe (1957); *Financial Intermediaries in the American Economy since 1900*, by R. W. Goldsmith; *Capital in Transportation, Communications and Public Utilities: Its Formation and Financing*, by Daniel Creamer, Sergic Dobrovolsky, and Israel Bovenstein (1960); and *Trends in Government Financing*, by M. A. Copeland (1961).

with the interpretation which Kuznets places upon the historical data and with the reasoning he uses to buttress his interpretation.

As a presentation of a mass of factual data, *Capital Formation* is admirably organized. After two introductory chapters, covering concepts and definitions and the difficulties of isolating long-term trends, the volume proceeds to examine the following major topics: (1) Trends in total capital formation, gross and net, and in relation to output, population and labor force; (2) the structure of capital formation, by type of capital good, by category of user (business, household, government) and by industrial sector; (3) the share of internal funds in the financing of capital formation; (4) the structure of external financing; and (5) Burns-Kuznets long swings in the major variables discussed in the prior chapters. The final two chapters present a convenient summary of findings and a brief discussion of the implications of the data for an evaluation of the future.

The major factual results (there is such a wealth of data that any selection may do an injustice to someone's particular interest) are as follows:

1. The share of gross investment in GNP, since 1870, has been steady at about 20 per cent, when measured in current prices, and has declined moderately when measured in constant prices; i.e., the relative price of capital goods has risen.

2. The share of net investment, in NNP, with both variables measured in current prices, has declined sharply, from about 15 per cent in the post Civil War decade to 7 per cent in the 1946-55 period; the share, measured in 1929 prices, has fallen somewhat less steeply, from 13 per cent to 9 per cent. As is clear from the difference in movement of gross and net investment, capital consumption allowances, as a percentage of gross investment, have risen substantially.

3. The over-all net capital-output ratio rose between the 1870's and the 1920's and then declined to the post second World War decade. Within this total there was a steady and dramatic decline of the net capital-output ratio in regulated industries (from 23.6 in 1880 to 2.5 in 1948!).

4. The decadal rate of growth in the capital stock declined steadily during the period (cycles aside). The rate of growth in capital per member of the labor force was fairly steady during major subperiods up until the late 1920's. Between 1929 and 1955, however, the rate of growth in the capital-labor ratio fell steeply. Despite this decline in the rate of growth in the capital-labor ratio, the rate of growth in output per worker did not fall off significantly, and if Department of Commerce figures on GNP are used, actually rose slightly compared to earlier periods.

5. The fall in the share of investment in NNP is almost solely due to the behavior of construction. Producers' durable equipment investment holds up quite well. The proportion of total business investment accounted for by equipment has risen sharply particularly since the 1920's. Similarly, the decline in the capital output ratio since the early 1920's seems to be mainly in the form of a lower ratio of construction to output, and not of equipment stock to output.

6. Total internal financing as a percentage of gross investment showed no

discernible trend, although it fluctuated from period to period. Considering only business investment, internal financing rose slightly. Equity financing declined erratically as a percentage of total external financing of corporations.

7. Long swings, with approximately 20 years between peaks, are discernible in population growth and in population-sensitive investment (residential construction and railroad capital formation). Other investment shows less evidence of long swings; such swings as can be isolated move out of phase with population-induced investment before the first World War and in phase after First World War.

There are a number of tantalizing questions raised, and hypotheses suggested by these phenomena. One of the most interesting questions is posed by the fact that the rate of increase in the capital-labor ratio fell sharply between the 1920's and the postwar period, while the rate of increase in output per unit of labor was not similarly affected. If we follow the lead of Solow, and the similar analyses of Kendrick and Denison, distinguishing movements along a production function—capital increases relative to labor—from shifts in the function, the Kuznets data suggest that the rate of outward expansion in the function has speeded up in recent decades; i.e., a given increase in the ratio of output to labor has been accomplished with a much smaller increase in the ratio of capital to labor. In looser terms, the place of technological advance, of improvements in the quality of the labor force, etc., have accelerated.

Further thought, however, suggests an alternative—or perhaps associated—hypothesis. As Solow has stressed, advances in technology and general knowledge are incorporated into the production process largely through investment in capital goods. The increasing importance of short-lived producers' equipment relative to long-lived plant in the business capital stock, implies a faster turnover of capital stock. Given some rate of advance in "best practice" technology and organization, the rising share of producers equipment has led to a decline in the average age of the capital stock and to a speedup in the average rate of replacement. In turn, other things being equal, this implies a faster rate of adoption of new technology, and finally a larger rate of increase in output per man-hour, per unit increase in the net capital-labor ratio. Thus the fact that the rate of increase in output per worker has remained roughly constant while the rate of gain in net capital stock per worker has fallen sharply, may be explained both by a more rapid advance in the technological frontier and by a more rapid rate of adoption of new technology. These kinds of considerations lead to the tentative conclusion that the stability of the gross investment share of GNP may be more significant than the decline in the net investment share which Kuznets tends to emphasize.

There is one major theme which runs throughout *Capital Formation*, namely, that the share, and changes in the share, of investment in total output are to be explained mainly from the supply side. In other words, the supply of saving rather than the demand for capital has been the major determinant of investment behavior. According to Kuznets, the major puzzle to be explained is why, "... if real product per capita grew 20 per cent per decade, the long term net national saving rate was below 15 per cent; why it declined instead of rising; and why the share of gross capital formation in gross national product barely ex-

ceeded 20 per cent and at best showed only a very slight rise, even for current prices volumes." His own answer is that the essential restraint on capital formation has been a limitation of the supply of saving rather than of the demand for capital, and hence it is the former which primarily needs to be explained in order to understand the growth process. This idea permeates Kuznets' discussion of the historical data, and provides the major thesis for his final chapter which looks into the future. The following, rather lengthy, quotations give the spirit of this interpretation.

But granting the usefulness of these hypotheses, one may still doubt that technological factors are dominant in determining the long-term trends in *nationwide* capital formation, or nationwide capital-output ratios if by technology we mean inventions and improvements associated with the stock of engineering and other knowledge. For economic and other considerations—changing pressures and forms of organization—exercise a major influence on the trends as well as on the levels of the capital-output ratios. Repeatedly in the past, great improvements have been effected in utilization of capital under conditions in which the technological framework has remained unchanged—as in the United States during the 1930's. In the course of its long-term economic growth, a nation can choose between high and low capital-output industries, and its choice will be made in the light of availabilities of resources for capital formation, that is, largely in terms of the costs of withdrawing them from current consumption. With such a choice, and the changing conditions that affect it, long-term trends in nationwide capital-output ratios may well reflect trends in the supply of savings much more than trends in capital presumably required technologically by some pattern of relations between specific baskets of final products and capital indispensable for producing them. (Pp. 89, 90.)

In particular, when we consider the large stock of new knowledge awaiting productive exploitation and the wide investment opportunities abroad that presumably existed throughout most of the period under discussion, it is difficult to assume that the level of capital formation and the factors behind the stability of the gross capital formation proportion and the decline of the net capital formation proportion are the results of long-run limitations upon the supply of capital investment opportunities.

The alternative approach, which emphasizes the supply of savings, seems more plausible and more fruitful as an analytical lead. Given the limited relative contributions to nationwide savings that, under our institutional conditions, could be made by corporations (in the form of undistributed profits) and by governments, the main question suggested by this approach is why the ultimate consumers in our rapidly growing economy managed to save only a small proportion of their income (at best slightly over 10 percent), and a proportion which, on a net basis, declined rather than rose, despite rising real income per capita. (Pp. 397-98.)

As Kuznets himself points out, the analysis of the *ex post* investment share must proceed, like any demand and supply analysis, by considering both blades of the Marshallian scissors. The only meaningful way, therefore, of interpreting the conclusion that the supply of savings, and not the demand for capital, was the major determinant of capital formation, is that the demand

for capital is highly elastic with respect to the interest cost of obtaining it, while the supply of saving is quite inelastic with respect to the interest rate. But Kuznets' analysis does not, fundamentally, establish this conclusion.

In general, Kuznets' argument seems to run as follows: If we think of technology as specifying a fixed relationship between capital and output, then technological considerations are not sufficient to determine the country-wide demand for capital. Purely technological constraints are clear only if we deal with single products, and even here wide variation in capital-output ratios are possible. And when we deal with a variety of products, the divergence between some minimum capital-output ratio and the one actually realized becomes even larger, because if capital funds are readily available the economy will emphasize the more capital-intensive industries and vice-versa. In essence this line of reasoning says that there are many economic aspects to capital formation in addition to the engineering facts of the production function, and that we must look at the supply of saving to pick up these economic considerations.

There are a host of problems in this approach. In the first place the *demand* for capital involves far more than engineering considerations. If we think of technology as specifying the parameters of the production function, then the specific choice of capital-labor ratios, and hence of capital-output ratios will depend upon the marginal rate of substitutability specified by the parameters, upon the relative prices of capital goods compared to the price of labor and of output, and finally upon the cost of obtaining funds. As technology advances, the marginal and average product of capital curves shift out, and further substitution of capital for labor may occur, depending on the magnitude and slanting of the shifts. With this framework in mind there are a number of developments which might have encouraged a decline in the capital-output ratio, and a reduction in the rate of increase in the capital-labor ratio in recent decades. Each of these developments operates upon the demand for rather than the supply of capital.

1. Prices of capital goods have risen relative to the over-all GNP deflator. The price of capital has thus fallen less, relative to the real wage rate, than would have been the case had relative prices of capital goods stayed unchanged. In Harrodian terms, technological progress has not been neutral, because, apparently, innovations have not proceeded as rapidly in the capital-goods producing industries as they have in the capital-goods using industries. As a consequence there has been a rise in relative prices of capital goods, and at the same interest rate, a fall in the capital-output ratio (capital and output both being deflated by their own prices).

2. The large rise in corporate profits taxes since the 1920's has raised the before-tax yield needed to achieve a given after-tax yield. For any given rate of technological advance, and a given interest rate (or a given minimum reservation yield) this should lead to a slower rate of substitution of capital for labor and a fall in the capital-output ratio relative to what would otherwise have been the case.

3. The shift between long-lived construction and short-lived producers

equipment—*ceteris paribus*—might be expected to lower the net capital-output ratio.² Similarly the dramatic fall in the capital-output ratio in the regulated industries from the late 19th century when there was substantial building ahead of demand, could be cited as a reason for the over-all decline in the capital-output ratio. Both of these might seem, at first, to be factors on the demand for capital side. Kuznets, however, points out that such changes need not be accepted as evidence that demand factors were the important determinant. In the first place, the *ex post* developments noted above may have themselves stemmed from a shortage of saving. In so far as they did not, they may simply have freed capital for use elsewhere. In particular, Kuznets stresses the availability of saving as a factor in determining product-mix; i.e., a plentiful supply of saving encourages the output of capital-intensive industries and vice versa. The mechanism presumably works through a Ricardo-Hayek type of response, in which changes in relative factor prices lead to changes in relative product prices, and thereby encourage substitution in the product market. The nationwide elasticity of substitution of capital for labor, in other words, depends not only on the elasticities implied by individual production functions, but also on the cross-elasticities of demand among various products. Theoretically, it is indeed possible that the developments referred to above are not independent explanations of the decline in the capital-output ratio and in the investment share. However, it is difficult to imagine that movements of such a magnitude were themselves caused by changes in savings schedules. Indeed, if such major developments had been caused by factors operating on the supply-of-funds side, we should have observed a sharp rise in the interest rate; as a matter of fact "riskless" interest rates have declined. Conversely, to the extent that such developments were not caused by changes on the supply-of-funds side, but represented shifts in demand schedules, they freed capital for use elsewhere. Kuznets' argument implies that, had saving propensities remained unchanged, such capital would have been used to maintain the over-all investment-share and capital-output ratio, especially via its encouragement of capital-intensive industries. However, in view both of the relative magnitudes involved, and of the relatively modest proportion of total price accounted for by actual (and imputed) interest costs, his argument implies the existence of a number of capital-intensive industries with extremely high long-run price elasticities of demand. It is impossible to state that he is wrong about this. I would suggest, however, that the burden he has placed upon relative elasticities is probably greater than they can sustain.

I do not mean to imply that the above explanations are necessarily the

² As a matter of fact, the relative increase in the price of construction relative to the price of capital goods is one possible reason for the shift from construction outlays to equipment outlays. In turn these relative price movements may be explained by the failure of productivity in construction to rise along with productivity in the equipment industry. While these are factors which reflect change in supply conditions in the capital-goods industries, they are not associated with the *supply of saving*. In setting up a demand schedule for *saving*, these factors are included on the demand blade of the scissors.

only ones, or even the correct ones, for the fall in the investment share and in the capital-output ratio. But they do illustrate the fact that one cannot set up a simple dichotomy between "technological" and "economic" considerations, and assimilate all of the latter under the heading of the supply of saving.

In his interpretation of the level and movement in capital formation, Kuznets comes face to face with the fact that "riskless" interest rates have declined during the period in question. How explain this, while at the same time maintaining that it was a decline in *ex ante* saving which brought about the decline in the net investment share? According to Kuznets, "like all prices they [i.e., interest rates] measure only the *relative* pressure of demand upon supply." Hence the decline in interest rates "means simply that the shortage of the supply of saving relative to investment opportunities has become less acute. Or to put it differently: with the economic growth of the country and the increased supply of goods per capita, would-be savers give a relatively lower preference to present supply than to future supply." This is indeed a most intriguing theory of prices. I had always been under the impression that the excess of demand over supply determined the direction and rate of change in prices, and that a decline in excess demand to some lower, but still positive, amount would slow up the rate of change, but certainly not lead to a price decline. As a matter of fact, if the (relatively inelastic) supply schedule of saving has shifted out to the right, as the prior quotation implies, and if there has been a decline in interest rates, and finally if this has been accompanied by a *reduction* in the *ex post* share of investment and saving, the conclusion which seems forced upon us is that the demand for capital has shifted down substantially (and/or, as noted above, the imposition of a sizeable corporate profits tax has had the equivalent effect of a large rise in the interest rate at all points on the supply-of-funds schedule). Moreover, even if we should accept Professor Kuznets' theory of prices, and agree to consider the decline in interest rates as only a reflection of a fall in the *excess* demand for capital goods, how do we reconcile a shift out to the right in the savings schedule with an *ex post* decline in the investment share? Excess demand implies an unsatisfied demand; if demand has been unsatisfied, should not a shift to the right in the savings schedule lead to larger *ex post* investment? Finally, if, averaging out the cycle, *ex ante* investment exceeded *ex ante* saving throughout the period, but the amount of the excess declined in the latter part of the period, how do we explain the contrast between the secular price decline of the last part of the 19th century and the secular price rise of the 20th century to date?

As a matter of fact, the savings schedule has *not* shifted out to the right; indeed its leftward shift forms the main burden of Kuznets' argument in other parts of the book. Personal savings, as Professor Kuznets points out, constitutes the bulk of the net saving total. Although the proportion of disposable income saved does not appear to have declined very significantly over the last seven or eight decades, and indeed the same proportion may now be forthcoming at lower interest rates, the share of disposable income in total income has fallen

noticeably since the 1920's, chiefly due to the increase in the level of taxation. Similar developments have occurred with respect to net corporate saving. Hence the over-all saving schedule has probably shifted to the left. But again, to reconcile this with a fall—or even stability—in the interest rate requires that we postulate a decline in the demand schedule for capital goods.

Kuznets may be correct that the fundamental limitation on capital formation has been the supply of saving. The accompanying implication of a very high elasticity of the demand-for-capital schedule in terms of the cost of obtaining funds may also be a correct one. As Kuznets himself states, in a number of places, *ex post* data on shares and ratios cannot “prove” the case one way or the other. However, in the judgment of this reviewer, the arguments which are advanced in *Capital Formation* for the primacy of the supply of saving in determining the historical trends in investment are not convincing.

In the final chapter, Kuznets examines the historical evidence in the context of the light it casts on possible future developments. In keeping with his major theme, he expects a continued excess of *ex ante* investment demand over *ex ante* saving. According to Kuznets, ours is an economy, “in which the recently increasing diversion of product to current consumption by governments, combined with high levels of consumer demand, has limited capital formation and savings proportions and brought about, under conditions of full employment, rising price levels which have persisted even through the 1958 recession.” Extrapolation of inflationary pressures over the next thirty years “raises a specter of intolerable consequences, making the policy solutions adopted critically important. . . .”

Those who share Kuznets' vision of the savings-investment process will doubtless find much with which to agree in this preview of the future. On the other hand, many, among whom this reviewer is to be counted, will not accept this interpretation of the past, or this prevision of the future, even when accompanied by the impressive marshalling of data which features *Capital Formation*. While the past five years are a short period indeed, in the sweep of time covered by the Kuznets volume, the events of those years certainly do not lend support to the picture of chronically exhilarated economy. The events of the postwar period, even including the last five years, have not justified the Keynes-Hansen fear of persistent secular stagnation; neither, however, do they warrant an acceptance of its converse, secular-demand inflation.

Capital Formation is an important work. Precisely because it is so monumental in scope, we have had to concentrate on a few central points. Since this reviewer disagrees with those points, the major part of the review has been critical. In the space allotted, it cannot do justice to the literally scores of cases in which *Capital Formation* provides significant and illuminating insights into one aspect or another of the capital formation process. The consequent imbalance of the review should not obscure the major contribution to economic knowledge which Kuznets and his colleagues have accomplished.

CHARLES L. SCHULTZE

University of Maryland

Decision Order and Time in Human Affairs. By G. L. S. SHACKLE. Cambridge: Cambridge University Press, 1961. Pp. xiv, 302. \$6.50.

In this book Professor Shackle, the founder and managing director of the "focus element" school of expectational economics, presents a report on the present state of development of that enterprise.

He performs this task by a careful and systematic restatement and elaboration of his basic concepts (as previously developed in *Expectation in Economics*, *Uncertainty in Economics*, and a variety of journal articles) and by a presentation and evaluation of various points raised by reviewers and critics of the previous writings. As usual, Shackle states his case with great lucidity, elegance, and persuasiveness; and he appraises the views of his various critics and friends with accuracy, generosity, and courtesy.

The following, in over-simplified form, are Shackle's major propositions.

1. A decision-maker, in contemplating the variety of possible outcomes of a prospective act, tends to array them on a line according to the degree of "gain" or "loss" that a particular outcome represents as compared to the present "viewpoint" situation. He uses this one-dimensional view of outcomes to introduce order and simplicity in what otherwise would be a complicated and confusing prospect.

2. To each point along the satisfaction-line the decision-maker assigns a degree of "potential surprise," reflecting the extent to which he would be surprised by the occurrence of the indicated gain or loss consequent upon his action. Potential surprise ranges from zero (when the outcome is "perfectly possible") to a value \bar{y} , denoting maximum surprise (when the outcome is considered totally impossible). Potential surprise is not a distributional variable, i.e., its metric is not like that of a probability measure. The potential surprise values of the various outcomes do not need to sum to one or to any other constant; and there is no limit to the range of outcomes that can have zero, maximum, or intermediate values. In the general case, potential surprise is zero for a range of gains and losses adjacent to the "viewpoint" state of affairs, and then, in approaching the positive and negative extremes, rises to the maximum, \bar{y} .

3. In viewing the range of logically possible outcomes of a given act, the decision-maker does not pay equal attention to all of them, as he would when applying a probability scheme to his decision. The power of a potential outcome to attract his attention varies directly with its positive or negative distance from the "viewpoint" and inversely with the potential surprise attaching to it. Two points of maximum attention-focusing power (called "focus elements") emerge: an extreme positive outcome and an extreme negative one. Both of these focus elements are somewhat beyond the range of "perfectly possible" outcomes. They occur at a point where potential surprise is already on the upgrade but has not yet risen as high as to make the outcome appear fanciful and unreal.

4. When preparing to chose from among a set of possible actions, the decision-maker considers only the focus gain and focus loss attaching to each of the acts. He refers each of these pairs to a two-dimensional "gambler's indifference map" (on which focus gains and focus losses are the two dimensions) and adopts that action whose pair of focus elements ranks highest with respect to his particular indifference curves.

Shackle's detailed discussion demonstrates that, in recent years, this concep-

tual structure has grown from a few seed-corn ideas into an academically respectable system of thought, complete with sets of axioms, a calculus of reasoning, and its own geometry. It has weathered the test of searching examination and criticism, and has evolved into an aesthetically pleasing, logically consistent, and well-elaborated system. Furthermore, it has been well grounded in a suitable philosophy of the historical process, in which decision is seen as the locus of continuing creation in the unfolding of history.

Shackle's concept of decision is such an interesting and well-prepared pudding that one would very much like to see it proved in the eating. This proof has not yet been provided; and Shackle perhaps does his own cause an injustice by appearing to be not very much interested in such mundane considerations. By eating we mean here some effective *use* of the concept either as a guide to *empirical research* on the decision process or as a foundation for *normative prescription*.

Concerning the use of the concept in psychological research, it ought to be possible to construct experiments in which the experimenter somehow manipulates the desirabilities and credibilities, in the subject's view, of various outcomes of his actions, with a view to discovering the existence and location of focus-outcomes and their effect on behavior. This reviewer attaches zero potential surprise, though only medium probability, to two results of such experimentation: first, the vindication of Shackle's framework, and second, the discovery that the framework needs to be enlarged by a theory of learning in order to attain maximum usefulness.

Pending the design and execution of such experiments, however, Shackle or one of his followers might usefully survey the already existing literature in psychology on the subjects of perception, learning, and motivation, and then test their concept of decision-making for consistency with this body of empirical knowledge.

It is also perfectly possible that Shackle's framework might yield prescriptions for decision-making. (Shackle himself would probably deny this, since, in his view, decision-makers already conform to his model.) Decision-makers who attempt to apply statistical probability theory or game theory in actual decision-situations quickly discover that this is a complex, costly, and time-consuming undertaking. It would be a great boon if a simplified scheme such as Shackle's could be demonstrated to perform quite satisfactorily as a substitute. Here, too, one can conceive of some interesting experiments for testing the adequacy of various decision-formulating schemes in various decision-requiring environments. Focus elements might well emerge as an entirely satisfactory scheme, especially if they are placed in some kind of Bayesian process for their reformulation on the basis of experience.

SIDNEY SCHOEFFLER

University of Massachusetts

The Measurement of Social Welfare. By JEROME ROTHENBERG. Englewood Cliffs, N. J.: Prentice-Hall, 1961. Pp. xii, 357. \$7.95.

Practical men or men in authority, lured to this book by its promise on the title page of "a new and constructive approach to welfare economics as a prac-

tical aid to social planning" will be disappointed; but academic scribblers, looking for a detailed, careful and critical survey of the more abstract aspects of recent controversies over "utility and all that" will be rewarded. Part I sets out the basic problems: how can we formulate a Social Welfare Function (SWF) which (1) is internally consistent, (2) enables us to compare a large number of the possible policies and (3) corresponds to the values prevalent in society. These criteria of *consistency*, *power* and *relevance* are the basis of Rothenberg's judgment of SWFs. He discusses Bergson's and Arrow's approaches to social choice and argues that Arrow's SWF includes the Bergson Economic Welfare Function. (Though possibly irrelevant, it would be most interesting to have Bergson's view on this.) He explains clearly and examines critically Arrow's conclusion that the acceptance of individual values leads to an inconsistent standard. Much of the rest of the book is devoted to an attempt to by-pass this conclusion, and in particular to remove the condition of the Independence of Irrelevant Alternatives. Parts II-IV examine various formulations of criteria of social choice, including (a) the compensation principle, which claims to get along without distributional judgments, (b) "mixed approaches," which contain pronouncements on both production and distribution, and (c) cardinal analysis, which may help to overcome such contradictions as the paradox of voting by the use of measures of the intensities of preferences, and may thus enable us to aggregate individual values. Part V turns to a discussion of requirement (3), viz., the relevance of welfare criteria to the prevailing social values. Rothenberg argues that it may be easier to make empirical generalizations about the community's desired decision-making processes than about either interpersonal comparisons or social orderings (though easier to generalize about the former than the latter) and that consensus on decision-making processes may be sufficient for the construction of a SWF. The ultimate chapter, containing his constructive proposals, is exceedingly sketchy. It says, in short, that individual values, decisions about procedures and social institutions are not isolated but interdependent and mutually reinforcing. Although Rothenberg's presentation is obscured by heavy sociological jargon, a translation would, as far as I can see, run like this: we want certain things, but, cooperating with (?) and being opposed by others, we not only accept certain rules, but incorporate some of the values of others and their acceptance of the rules into our system of values. This system is not "given," but is modified by our learning from and getting fun out of cooperating. The rules about how common decisions are to be made are expressed in democratic institutions. From this it is somehow concluded that the decision-taking process is identical with the SWF. The transition from this process being part of the SWF to its being identified with it is not entirely clear. In any case, the customary means-ends dichotomy loses its force.

Nor is it clear why so much stress is laid upon consensus on the method of choosing an "official" SWF. It may be part of the prevailing values that conflict and struggle are desirable, possibly a condition of life, and should not be "resolved." Whence the value judgment that value judgments *ought to be* capable of being aggregated (even assuming that they *are*?). Further, it may be more fruitful to formulate SWFs for groups in society rather than for so-

ciety at large: SWFs for farmers, workers, professionals, suburbanites, the Liberal Party or small shopkeepers are more promising than a SWF for humanity (for why stop at the nation?). Rothenberg's own digression on family choice would suggest that only groups with strong solidarity are eligible. The power and relevance of economists' advice would be strengthened if their recommendations were based on such particular SWFs: they could even set up as welfare consultants with brass plates.

Although deep in the Anglo-Saxon tradition on these questions, Rothenberg does not appear to be fully aware of the revolutionary break with traditional welfare economics which his repeated plea for usability and applicability and his constructive proposals imply. Take only the traditional separation of "given" ends from neutral means. Rothenberg knows that it meets with at least four difficulties: (1) Ends are shaped, or at least partly influenced, by our opinions about means, and our views about means depend upon what ends other people and we pursue. (2) People do not know clearly their ends and attempts to clear up ambiguities and to remove ignorance must alter the ends. (3) If ends are based on false beliefs about means, fuller information will change the ends, but not in a logically determinable manner. (4) Not only do ends often turn out to be means, but means often take on the quality of ends.

But these crucial issues are treated in footnotes and asides (e.g., fn. p. 5, fn. p. 328, p. 329), while long chapters are devoted to types of analysis which are destroyed by such recognition.

Similarly, the basic criticism of consumers' sovereignty is not concerned with the "psychological needs of the organism" (p. 323), but with the fundamental problem raised by the March Hare: "You might just as well say that 'I like what I get' is the same thing as 'I get what I like'" (*Alice's Adventures in Wonderland*, p. 98). A system cannot be judged by the standards which it creates.

This lack of integration of, on the one hand, the insight of the last chapter and the pleas for applicability and relevance and, on the other hand, the traditional views is evident in several places. Thus Rothenberg attempts, rightly, to overcome the impossibility of welfare comparisons if changes in taste occur. But his method fails because it is based on a falsely rationalistic view of human personality, discordant with Chapter 13. If a person with incomplete knowledge and experience chooses in one way, and, with fuller knowledge and wider experience chooses differently, and if the latter choice could be *logically deduced* from the preferences revealed by the former, and thus an unambiguous preference scale be constructed, certain types of "changes in tastes" could be incorporated in a rigorous welfare economics. But the required process is not one of logical deduction but of psychological interpretation. Unambiguous welfare conclusions are impossible without a much fuller theory of human personality and, analogously, of the "personality" of groups. This argument reinforces the use of "particular" SWFs (though mere consultants may not have the required empathy).

Similarly, Rothenberg's argument that the distinction between "tastes" and "values" coincides with that between absence and presence of external consumption effects is convincing, as far as it goes, but it does not go far enough

in the light of his own proposals. There can be no unique ordering of an individual's preferences, for the reason that one ordering (say, that expressed in impulsive market choices) may be subject to self-criticism (possibly expressed in cool market choices) which in turn may be exposed to self-criticism (perhaps expressed in voting) and that any ordering, expressed in any way, may be subject to self-criticism in the light of higher standards, which standards themselves can be criticized. Interdependence then may take the form not simply of A's satisfactions depending upon B's consumption, but also of A's standards of criticism ("values") depending upon B's standards. A healthy society consists of critical and self-critical citizens who attempt to clarify and criticize their values in the light of the—similarly self-criticized—standards of others. Chapter 13 seems to point towards such an interpretation of Rousseau's General Will and the Quakers' sense of the meeting, which is neither mystical nor indeterminate. But nothing of this is reflected in the earlier Appendix on "Welfare Comparisons and Changes in Tastes."

Of the numerous issues Rothenberg raises in his stimulating appraisal, only one or two can be taken up. He says (correctly) that relative distribution cannot be measured on a diagram showing utility possibility curves (p.64). But all that is needed are value judgments on different distributions. A curve can be drawn linking distributions which are deemed to be equally good on distributional grounds. Assuming the independence of utility-possibility (u) and "equally-good-distribution" (d) curves (an unwarranted assumption), a social indifference curve between points showing different u - d combinations can be constructed.

In his evaluation of the compensation principle Rothenberg argues that even if the separation of production from distribution were possible, it would not be useful (p. 102). Again, this is surely not so. It would be most useful if aspects of production could be separated from aspects of distribution, even though no categorical recommendations could be made unless the two aspects were combined. Hypothetical recommendations based on expert knowledge are not useless. To reject them is to reject the division of labor and, more particularly, the economist's function of helping people to think clearly about what is involved in their choices. The social indifference curves suggested in the previous paragraph between different u - d combinations need not (perhaps should not) reflect unanimously accepted group values. The area of conflict would be clarified (not eliminated) if we knew whether we objected to a policy because it reduces utility-possibilities more than it improves distribution, or because it worsens distribution more than it increases utility-possibilities.

Rothenberg's treatment of these problems suffers from ignoring Little's second edition published in 1957. He also pays relatively little attention to foreign contributions to the literature. Myrdal, whose cumulative process, adapted from Wicksell to sociology, is described on page 315, whose approach has certain features in common with Rothenberg's, and whose *American Dilemma* demonstrates how a "powerful" and "relevant" SWF can be used, is not even mentioned in the 16-page bibliography. (I hope that the omission of my own "Programmes and Prognoses," *Quart. Jour. Econ.*, Aug. 1954, and of my article in *Économie Appliquée*, Oct.-Dec. 1952, which, very inadequately and

partly fallaciously, points in the same direction as Franklin M. Fisher's analysis discussed in Chapter 5, has not prejudiced me towards overemphasizing other omissions.)

While reading the full and subtle discussion of cardinal analysis and the various attempts to measure utility, I asked myself why, instead of Preference Thresholds and Expected Utility, the following simple method could not be adopted: Put before an individual the following hypothetical question: you can have \$1,000 in year 1 and \$100 in year 2. If you were given an extra \$1 in year 2, how much would have to be taken away from you in year 1 in order to make you no better and no worse off in the two years combined? If the answer is, say \$20, we have established that the utility of, say, one "util" is derived from \$1 when income is \$100, and from \$20 when it is \$1,000. We would have to specify that income must not be stored in any form but must be spent and consumed during the year. Uncertainty and time preference must be eliminated by asking the individual to abstract from them. His obedience is verified if we get the same answer when the sequence of the two years is reversed.

Produktivitet och räntabilitet. Studier i kapitalets betydelse inom svenskt näringsliv. (Productivity and Profitability. Studies of the Role of Capital in the Swedish Economy.) By ERIK LUNDBERG. Stockholm: Norstedt, 1961. Pp. 286.

During some fifteen years in the 'thirties and 'forties, a steel mill belonging to a large Swedish company was left to operate without any new capital investment or technological change. Maintenance and replacement were kept at a minimum. Output per man-hour in this plant at Horndal rose by almost 2 per cent per annum. In other plants, significant investment projects were carried out, and output per man-hour in the company as a whole rose by almost 4 per cent a year.

The "Horndal effect" provides a concrete illustration of at least part of the problem of "pure" productivity increases, residual to conventionally measured inputs of capital. On this area, much effort is now converging, and Erik Lundberg's new book contains a discussion of it. According to his findings, output per man-hour in Swedish manufacturing industry rose by 2.2 per cent per annum in 1946-57. About 45 per cent of this increase is attributable to increased capital intensity, and the remainder, or approximately 1 per cent per annum, should represent pure productivity increase. This is a slightly lower rate of "technical progress" than that found in American series which show a rate closer to 2 per cent for recent years and suggest that over the last half-century close to 90 per cent of the increase in output per man-hour has been due to other factors than increased capital intensity in the ordinary sense.

"Productivity" is one of the themes of this book, but the statistical measurement of productivity is impossible without estimates of capital stock and without a good deal of capital theory, implicit or explicit. As Lundberg says,

"in all economic thought there is probably no concept more confusing, more nebulous and obscure, more complex, more variously understood by economists through the ages, than the concept of capital." All economists with any interest in empiricism face the conceptual problems of capital theory, and all move on, as they must, to construct models as if it were clear what capital really is and to employ statistics as if they really measured it. Lundberg does too in the end, but only after an unusually searching enumeration of the intellectual difficulties that it involves and after asserting that the value of capital stock simply cannot be unambiguously defined except in a static context where the future is predictable without uncertainty. As for the use of production functions, his own assumption, based on interviews with industrialists and technicians, is that suboptimal disequilibrium in regard to technology and the utilization of existing capital stock is a profoundly important aspect of the situation at any time, and that the dynamics of capital accumulation can only be understood in terms of such disequilibria and the profit opportunities they imply.

A second theme is "profitability" which is discussed on the basis of a questionnaire and interview study of investment planning in Swedish industry. In a large number of firms, even very sizable investment projects were evidently carried out without any estimates of rates of return or even payoff periods. Office buildings, workers' housing, inventory increases—such investments simply do not lend themselves readily to the application of precise criteria. In the introduction of new equipment, smaller firms may be entirely justified in imitating successful competitors, and even large enterprises may on the same grounds adopt products and processes launched abroad. Where systematic criteria were employed, however, the general impression was much like that familiar from a number of American studies: payoff periods were expected to be less than five years, rates of return (before tax) of 20-40 per cent were usually required. But the range in these expected rates of return was extremely wide—from 3 to 70 per cent—and, moreover, *realized* rates of return were very much lower than anticipated ones.

Lundberg asks why this should be so, and his answer puts particular stress on the many kinds of interdependence which inevitably mar attempts to anticipate returns to individual investment projects. The profitability of new equipment depends on the existence of complementary plant facilities, possible bottlenecks and disequilibria, etc., and cannot be compared with anticipated returns on long-range expansion projects. (Nor do they seem to be thus compared by managers who do not neglect long-run projects with lower anticipated returns in favor of more profitable short-run expansion of a piecemeal character.) Long-run plans for expansion will be affected by expectations of external economies arising from growth in other industries and in the public sector. And *ex post*, the interdependence among competitors, both in product and factor markets, will depress returns below those expected at the time of investment and deflect the benefits of capital accumulation toward consumers and labor.

But, no matter how the contribution of capital is measured, that contribution will depend on the allocation of scarce capital among competing investment opportunities. In the third part of his book, Lundberg raises the question

of how efficiently the markets for capital and credit actually perform this function. The principal task of the Swedish credit market is to transfer surplus liquidity from other sectors to the government and the housing sector which together absorb about three-quarters of the loanable funds. This can hardly be described as even an approximation to a perfect market. The stock market is narrow, the bond market often strictly controlled, and corporate investment very largely self-financed for a variety of well-known reasons. In such a compartmentalized market, the mobility of capital is bound to suffer, and in the field of policy Lundberg makes a plea for measures that would restore mobility to this factor, just as in Sweden much effort has been devoted to the stimulation of mobility in the labor market. Tentatively and provocatively he advocates a policy of low taxes and high interest rates that would reduce at least some of the barriers that presently impede the flow of savings from finding optimal uses.

Although this book is partly based on Swedish materials and is addressed to a Swedish audience, Lundberg's assessment of the state of economic thought on capital and growth is of general interest. "Technical progress" is often built into exponential terms in a production function but Lundberg set out to investigate the way in which productivity increases emerge in the individual cells of the economy and to build bridges between the ideas of business men and managerial economists on the one hand and macroeconomics on the other, between traditional capital theory and recent growth models. Skepticism is the hallmark of his discussion of macroeconomics, its models and statistics. Between the esoteric realm of capital theory and empirical estimates or policy recommendations there lies a "sea of troubles," and Lundberg misses no opportunity of stressing the wretched fragility of the conceptual floats on which we paddle across those metaphysical depths. But, as he characteristically remarks, a proposition may be interesting without being true, and no one could be more sensitive to the urgent demand for answers to impossible questions. There remains nevertheless a tension between the desire for intellectual clarity and the sense of relevance and responsibility, and it is this tension that stamps and enhances Lundberg's writing. A contribution that sweeps with such lucidity and ease from the basic premises of economic analysis to the exigencies of policy belongs in the greatest tradition of economic thought.

GORAN OHLIN

Columbia University

Household Saving and the Price Level. By STEN THORE. Stockholm: National Institute of Economic Research; Almqvist & Wiksell, distributor, 1961. Pp. 91. SKr. 30.

The central proposition upon which this volume is based is that prices have too long been neglected in the theoretical and empirical analysis of household behavior. The author proposes to reinstate the price level as an explicit determinant of consumer demand and savings, with his own interest particularly concerned with the latter. The series of multiple linear regression models which are the core of the book are designed to determine the magnitude of price effects on saving.

The introduction points out that, since the advent of Keynesian consumption and savings functions, emphasis has been almost exclusively on the income effect, with prices disregarded in cross-section analysis and eliminated in time series by what is termed the "deceptive device" of deflation. The author returns to the neo-classical theory of demand of Marshall, Pigou and others of the Cambridge School in which both price and income effects are explicitly considered. One of his chief aims is the development of a dynamic price theory which can be used to determine the effect of continuous inflation, such as occurred in postwar Sweden, upon household saving. At the end of the volume he concludes that the application of his models to Swedish data on savings indicates that a 3 per cent annual increase in the price level of consumer goods would decrease average household saving by at least 9 per cent per year (p. 240).

The seven chapters of the book contain a series of progressively more complicated regression models. The procedure in each case is to define a consumer preference index for the individual household, develop a statistical probability or regression model and test the model by applying it to data on savings, largely from Swedish surveys in the 1950's. The simplest model (Ch. 1) is a one-period model including consumer prices, planned consumption expenditure, planned holding of bank money, expected disposable income and initial holdings of bank money. Saving is defined as bank money and/or shares of stock and does not usually include durable goods. The succession of models which follow provide not only an interesting exercise in model building for the student of regression analysis, but some critical appraisal of their application. There are lagged models; models in which expected income (the Lindahl "subjective" income) and future prices enter; intratemporal and cross-section models; and many more.

The material in two of the chapters seems especially relevant to current research in the area of consumer expenditures and savings. Chapter 3 contains a discussion of the learning process with reference to Katona's theory of habit formation, the Duesenberry demonstration and past income effects, the application of feed back to learning and the irreversibility of demand curves which may result from the learning process. This leads to the inference that identical consumer preference schedules cannot be assumed in cross-section studies and that cross-section models may, therefore, contain a "lack of specification" and produce misleading results. Can the introduction of demographic, psychological and other non-economic variables help? Thore poses this question, but seems, on the whole, to favor the view that economists should limit themselves to the analysis of "financial" variables, partly on the grounds that survey samples are seldom sufficiently large to permit the requisite breakdowns and partly because the use of such variables appears to him to lead merely to disaggregation of the Keynesian consumption function.

This view runs somewhat counter to the recent tendency, at least in the United States, to analyze consumer expenditures and savings in terms of many variables, some of them non-economic, and to the concern with interaction among such variables, which cannot be satisfactorily dealt with by the usual multiple linear regression models. It is interesting that Thore encountered a case of such interaction, between income and wealth, in the application of his re-

gression model (presented in 2.6, p. 66) to the Swedish 1957 savings data, but interaction does not appear to impress him as a significant general problem.

In Chapter 5 the permanent income hypothesis and the Keynesian consumption function are dealt with in great detail. It is demonstrated here that Friedman's formulation of permanent income (in which the M.P.C. of transitory income is assumed to be 0) is a special case of a more general multiple regression model with respect to permanent and transitory income. Thore joins with other critics who regard this assumption as unrealistic.

It is hardly possible within the confines of a brief review to deal with the many theoretical, statistical and empirical points covered within the volume. This book requires study. It should serve as a useful reference book for graduate and other students of household behavior and regression analysis. In addition to the nontechnical introduction and conclusion, and the main text, the book includes a statistical appendix on regression models and a substantial bibliography.

As a final comment, this reviewer would like to express some skepticism as to whether the assumptions of multiple linear regression analysis in its present form provide the most satisfactory tool for the analysis of household behavior. Nor does it seem possible to analyze effectively the determinants of consumption and savings without taking account of a number of variables, including many noneconomic ones, and their areas of interaction.

ELIZABETH W. GILBOY

Harvard University

Investment and Growth Policies in British Industrial Firms. By TIBOR BARNA.

New York: Cambridge University Press, 1962. Pp. viii, 71.

Post-War Investment, Location and Size of Plant. By P. SARGANT FLORENCE.

New York: Cambridge University Press, 1962. Pp. viii, 51. \$2.50.

These two monographs are products of the British National Institute of Economic and Social Research prepared by Mr. Barna of the Institute and Professor Florence of Birmingham University. Barna's monograph lends itself to a more extended review than Florence's purely statistical monograph.

Barna's monograph not only gives insights into the slow yet stable growth of the postwar British economy but also contains much that is instructive for the growth policies of the American economy in general and American industries in particular. On the basis of comparative investigations of two representative groups of British industries (i.e., "growing" electrical engineering and "stable" food processing), Barna draws interesting inferences regarding private investment decisions, and also makes suggestive generalizations respecting policy desiderata.

It is instructive that private investment decisions so relevant to Britain's (and other market economies') stable growth have been favorably influenced by her public policy of maintaining "a high and stable level of employment" and by increased competition (due to removal of wartime controls, antimonopoly legislation, and liberalized imports). Yet Barna candidly admits the continued existence of "a vicious circle of restricted growth, weak balance of payments and inflation," and also implies the preferability of "altering the re-

action pattern of the economy" over "detailed intervention" by the government—as the best way to break that vicious circle. For that "restricted growth" he seems to blame the static and conservative attitudes of British managements, and approvingly quotes Harold Laski's caricature of the British gentleman-merchant: "The gentleman would rather lose his income than his uniqueness." By way of urging more dynamic and progressive management attitudes, Barna makes the typical British understatement: "The management which resents the purchasing power of the working classes, which resents the increased role of women as consumers and which equally resents technological innovation in production and in distribution, is unlikely to be successful." Still, the reader may be left wondering whether the British economy will be able to grow faster merely through such a "managerial revolution" as Barna seems to recommend without at the same time adopting a more vigorous *public* policy for the growth of investment and productivity.

Turning now to Florence's monograph, the reader is informed that it represents a combination of an up-to-date statistical supplement to his previous *Investment, Location and Size of Plant* (1948), an additional supporter of the previous conclusion that "greater intensity of investment is associated with prevalence of large size of plant in any industry where location is free," and a further empirical basis for "public policy in helping the smaller plants to survive." The relevance of investment, location and size of plant to "the industrialization of the underdeveloped countries" claimed by Florence is not easily established by a mere compilation of statistical data or by statistical generalizations, however. It is a pity that Florence did not, in this connection, test the hypothesis that the location and size of plant are capable of affecting the secular behavior and structural stability of the capital-output ratio and hence of quantitatively influencing the national rate of growth of output. New comparative statistical data on British and American industries are carefully included and some relevant statistical techniques briefly discussed. Nearly one half of the Florence monograph is devoted to statistical appendices. Except to a limited number of statisticians this monograph by Florence is unlikely to prove very inspiring.

KENNETH K. KURIHARA

Rutgers University

Theories of Economic Growth and Development. By IRMA ADELMAN. Stanford: Stanford University Press, 1961. Pp. viii, 164. \$5.00.

Here is "neither a *theory* of growth nor a *model* of a growing economy. Rather . . . a structure . . . sufficiently general to treat the theories of economists as particular special cases" (p.7). The structure bears a strong and acknowledged resemblance to that of Haavelmo in his *A Study in the Theory of Economic Evolution*. We learn what view Smith, Ricardo, Marx, and Schumpeter took of the defined variables which are pretty much all-inclusive. Thus output is taken as in some sense related to the rate of utilization of the capital stock, to natural resources (subsequently an empty category), to the size of the labor force, to the fund of applied knowledge, and to the socio-cultural milieu. The last two are admittedly difficult to quantify but are of heuristic value.

The interrelationship of the variables is a "structure" of six equations. To handle the effect of discontinuities, differencing is chosen over differentiation (p.14) but, to simplify the exposition, the variables are taken as single numbers rather than as vectors and the production functions considered are assumed differentiable (p. 24).

The treacherous job of translating the masters then begins. We find that Smith regarded the sociocultural milieu as exogenously determined. Like others before her, Mrs. Adelman believes the essence of the *Wealth of Nations* to be "an unstable dynamic process . . . [whose] . . . fundamental determinant is the rate of capital formation" (pp. 39, 41). The treatment of Ricardo contains a citation, "one among several," which lead Mrs. Adelman to "see now that the Ricardian production function should not be restricted to one in which the technological coefficients are fixed" (p. 47). This is misleading enough to make one wonder whether interpretation has been clouded by the use of the term "capital-output ratio" though all is correct and explicit in the discussion of Marx. Blaug's *Ricardian Economics* seems a successful attack on the position taken by Mrs. Adelman when she asserts that "the Ricardian dictum that 'nothing can affect profit but a rise in wages' is merely a truism" (p. 54). Interestingly, the interpretation of Marx assimilates "changing relations of production" to an "index of the accumulated fund of applied technical knowledge" to include "some measure of the interaction between techniques of production and the social and economic organization of society" (pp. 61-62). After this daedal and dizzying step there follows a straightforward analysis of the Marxian system showing that "in the last analysis the clue to economic growth lies in the rate of capital accumulation" (p. 79). We find that "the evolution of a Marxian economy is uniquely determined by the initial conditions of the system and its structural parameters. There are no degrees of freedom in the system" (p. 89). Despite the predictive failure of the Marxian analysis, it "provides an excellent example of the power and importance of dynamic analysis" (p. 93). Under the template of the "structure," Schumpeter's model reveals that the rate of growth of output depends upon the exogenously determined rate of population growth, which fixes the trend of economic growth, and upon the history of technological progress. Almost without exception, works of originality and genius in the history of economic theory have been Augean stables of inconsistency. Tidying them up, one is bound to lose a few prize cattle. This is a pity but perhaps worth it if it leads to a deeper appreciation of the surviving stock.

To bring matters up to date there is a neo-Keynesian model which is considerably more neo than Keynesian. There are two actors, the labor- and entrepreneurial-forces. They receive respectively wages, which are wholly expended on consumption, and profit, including interest and rent, which is spent on consumption and investment. The factors of production are labor and capital. Full employment is assumed. Investment can affect productive capacity in the time period in question but population change can affect the labor force only in the "next period." The fund of applied technical knowledge and the sociocultural milieu are exogenously determined. The three relationships examined are the growth pattern of the labor force, the accumulation of capital,

and the growth of income. Assuming that population increases in response to an increase in the real-wage rate but that it tends to stabilize, the real wage can be explained by the capital-labor ratio. One of the determinants of this ratio is the saving-investment relationship which will be in long-run equilibrium when the natural and warranted rates of growth are the same. Familiarly, the production function is of the Cobb-Douglas type which permits the inclusion of increasing, constant, or diminishing returns. The impact of technological changes on possible shapes of the production function are examined. The conclusions are (1) that the "clue to the economy's long-run dynamic behavior may be found in its technical dynamism" (p. 133); (2) optimal population policy depends on whether the economy is experiencing increasing, constant, or diminishing returns; (3) labor-saving innovations can increase per-capita output or per-capita leisure; (4) a single injection of capital has no effect on long-run growth which is rather determined by the natural-rate-of-growth path but it can speed the approach to equilibrium. Dropping assumptions one by one, Mrs. Adelman is hopeful that careful study of the production function in a given situation may lead to sensible policy recommendations. The policy recommendations which in fact emerge would come as a surprise to no sensible person.

Coleridge spoke of poetic faith as a "willing suspension of disbelief." If, as Mrs. Adelman appears to, one has a poetic faith in index number theory, he will admire the generality of the reasoning and more especially the technical deftness and fine style which is neither over-terse nor diffuse. Even those who lack faith can admire these qualities but will sigh to read (at page 145): "The phenomenon of underdevelopment must be understood . . . in the context of the entire complex of interrelationships that characterize the economic and social life of the community."

ERSKINE MCKINLEY

Tulane University

Economic History; Economic Development; National Economies

Productivity Trends in the United States. By JOHN W. KENDRICK, with the assistance of MAUDE R. PECH. National Bureau of Economic Research, General Series, No. 71. Princeton: Princeton University Press, 1961. Pp. lii, 630. \$12.50.

A few years ago inflation was the major concern; today it's productivity. Almost (but not quite) equivalent to the raging debate over creeping inflation, today's press is filled with controversy over whether or not productivity gains should be used as a yardstick in helping to settle labor-management disputes.

Thus, it is timely to mark the appearance of Professor Kendrick's long-awaited book. For several years the National Bureau's significant work on productivity has steadily been made available in conference reports and occasional papers. But here, at last, is the basic underlying study. And, indeed, it was worth waiting for!

Unquestionably, these are the authoritative findings and methodology that

should determine the course of research in this area for many years. A long, detailed study, crammed with tables and appendices, this book looms as one of the most important and provocative studies published in the past decade.

To a considerable extent, its value lies in the painstaking care with which Kendrick has set up various productivity formulas and traced their relationships. At first, emphasis tended to be on the relatively crude but useful concept of physical output per man-hour. But the search for a better measure of *efficiency* (and productivity in this study is defined as "a measure of the efficiency with which resources are converted into commodities") coupled with more available data, led to the development of "total factor productivity," which utilizes input of both labor and tangible capital. It may not be the ultimate refinement, but in the words of Solomon Fabricant, it is "the best currently available approximation to a measure of efficiency."

Tracing the course of total factor productivity Kendrick finds that it has risen at an average annual rate of 1.7 per cent in the private domestic economy from 1889-1957. (This rate is somewhat lower than the weighted or unweighted rates of increase in output per man-hour because tangible capital input has increased at a faster rate than labor input.) However, this trend partially conceals the fact that the rate was 1.3 per cent from 1889-1919 and 2.1 per cent from 1919-1957. Since the end of the second World War it has been even higher. Looked at in a somewhat different light: since 1889 real private domestic product grew at roughly a 3.5 per cent annual rate. Thus, about one-half of the growth was accounted for by the efficiency of input utilization; the other half by additions to labor and capital inputs.

It is in the basic analysis that went into the derivation of these findings that one comes to appreciate Kendrick's impressive skills as well as the balanced research programs instituted by the Bureau. Tapping the material of literally dozens of earlier Bureau publications, the author goes deeply into the anatomy of American industry for specific illustrations. The electric and gas utilities showed the strongest productivity advances, along with nonrail transportation; while anthracite mining, lumber and leather brought up the rear. Services, too, showed lower productivity gains over this long period. However, during short spans, significant variations from these trends were noted.

Detailed appendices, as might be anticipated, comprise the bulk of the material. But the important findings are highlighted early and clearly.

How does one use a volume of this sort? For forecasters the study is a gold mine of relevant data, but the break in the productivity trend line raises nagging issues. In projecting the level of economic activity for, say, 1970 does one employ the very long relationship, or, perhaps, should the postwar experience be extrapolated? The difference might come to \$100 billion in GNP for the target year. Denison's recent study for the Committee for Economic Development is outstanding in its conservatism on this score, while the work of the National Planning Association and *Fortune* magazine highlight the more optimistic side.

Again, what of this matter of wage settlements and productivity yardsticks? In a spirited comment included in the volume, Bureau Director Stanley H. Ruttenberg of the AFL-CIO files several demurrers. He challenges the conceptual framework of total factor productivity, stating that it excludes many

intangible factors other than capital and labor. Among these he cites "education, science, technology, social organization, cultural heritage, and the quality of human skills and ingenuity which are essential to rising productivity." He also questions the "efficiency" approach of this concept in that it combines *actual* man-hours and *available* capital.

In fairness to Kendrick: at no point does he urge that the productivity yardstick be used in wage determination policies. He does, however, indicate that labor's share of private national income has risen, a finding that is consistent with the roughly long-term stability in the rate of return on capital. In addition, he demonstrates that prices have tended to rise less rapidly (or fall) in those industries which have shown more rapid productivity increases.

For the economist this is a volume to be carefully studied and considered. Fortunately, Solomon Fabricant has provided an excellent introduction which serves both as a survey of productivity analysis as well as an effective summary of Kendrick's work.

Here, then, is the solid foundation upon which future researchers will base their attempts to refine and provide more inclusive measures of productivity.

ROBERT A. KAVESH

New York University

Europe's Needs and Resources. By J. FREDERIC DEWHURST, JOHN O. COPPOCK, P. LAMARTINE YATES AND ASSOCIATES. New York: Twentieth Century Fund, 1961. Pp. xxvi, 1198. \$12.00.

Early in 1957 Fred Dewhurst first told me of his plans to do an *America's Needs and Resources* of Western Europe, to embrace the countries of the O.E.E.C., excepting Turkey but adding Finland. The study was to include a review of economic developments in the postwar period, some cross-section analysis, and projections to 1970 of the output potentials and demand patterns in terms of GNP's, as well as of some basic industrial sectors. I hope I conveyed my real enthusiasm for the project, as it was obviously the type of research of direct interest to us. But as we had recently finished a five-year projection for the O.E.E.C. Eighth Annual Report, I knew what a large job lay ahead. Hence, I did not minimize the size of the task or the statistical and other difficulties that would be encountered.

Dewhurst did not need any warning flashes; he knew the O.E.E.C. and E.C.E. reports, among others, that would provide a point of departure for the work and he knew his own capacity to see a large project through to the end. Besides excellent associate directors, he proceeded to get together a competent research staff, as well as an outstanding group of scholars to contribute to the research and writing on a part-time basis. Now, the years of patient work have passed and *Europe's Needs and Resources* has been published.

I am pleased to say that the volume immediately takes first place among the studies of the postwar Western European economy. It warrants not only the *médaille d'or* but also the *médaille d'argent*, for there is not another work that is a close second. Cast in an ample mold which requires 1200 double column pages, it is of great current interest and utility besides being a major work of reference.

While the study has the same framework and viewpoint as its American an-

cestor, the authors have been flexible in their adaptation to the European economy. After an introductory survey of Europe's postwar recovery, there follow 25 other chapters devoted to various aspects of the economy and two concluding chapters as well. The individual chapters cover all three phases of the study where appropriate, i.e. historical review, cross-section analysis and quantitative projection into the future, often supplemented by qualitative speculation about the character of economic developments that may be expected. Most chapters are supported by valuable appendices giving further statistical data and notes on sources and methodology.

The broad layout of the chapters was determined, it would seem, primarily to provide a logical flow of argument for the projections and is well suited to the aims of the study. After the first survey chapter, population and then manpower are dealt with. Then comes a general presentation of the gross national outputs and expenditures, followed by a series of ten detailed chapters on the major components of the GNP and selected subgroups. A few basic natural and industrial resources are then examined in five chapters, devoted to agriculture, forestry, fishing, energy sources and output, and minerals and metals production. Chapters on foreign trade and capital movements and on exchange and currency problems are followed by analytical descriptions of a few special subjects, i.e., underdeveloped areas, capitalism in the postwar period, productivity, technology, and economic integration.

This summary should indicate the wide scope of the volume. Of course, not every aspect of the European economy is treated and various views could be set forth about other aspects that one would have liked to see included. But, what had to be included to meet the objectives of the study, is included; possible changes in coverage relate to matters somewhat aside the main stream, like a few of the later chapters.

It is not feasible to appraise this vast body of material in detail and, indeed, hardly necessary. Almost all the chapters provide as a minimum a good synthesis of widely scattered material; and many (with their appendices) go well beyond that by contributing original research—leaving aside the projections which necessarily involve original research and judgments. The chapter and appendix on Housing, for example, is an obvious case of the best thing available on the subject. The one on Exchange and Currency Problems contains less that can be called new, but it is still more than a skillful synthesis because there emerge the reflections and conclusions of one who has deeply thought over postwar developments.

A few chapters seem to me less penetrating, an example being that on Capitalism in Postwar Europe. While of interest from a historical viewpoint, I cannot see that the judgments on the nature of capitalism, or on the degree of it in the various countries, tell much about the significant differences among the countries or about the paths they ought to follow. The reason is that the criteria used, such as the relative extent of public enterprises or of the instruments used in economic policy, are not analyzed in relation to the problems that had to be faced. There have been industries socialized because of a belief in socialism, but also enterprises taken over into the public sector to prevent the collapse of the private enterprises or public enterprises created to serve a function that was not being performed previously. The implications of these cases

are quite different, even from the standpoint of political ideology. Similarly, the need for policy instruments may be very different for a country which exports 40 per cent of its output than for one which exports 10 per cent. It is apparent also that a country may use more policy instruments as it learns to operate the economy to higher standards of stability and growth, while at the same time it strengthens the free enterprise spirit by promoting competition and reducing protection.

Current interest in the study will, without doubt, be centered on the projections, and it is to these that I would like to devote most of my allotted space. The method used is a familiar and sound one. The expected volume of employment at the end of the period was derived by starting with estimated population growth, adjusting for the various forces which may influence the participation of the population in the labor force, and then allowing for the projected decline in working hours and change in the ratio of unemployment. The volume of employment, together with the assumed rates of productivity increase, yielded the estimated potential GNP in 1970 for each country and these, weighted by exchange rates, gave the aggregate. The allocation of the potential GNP among the various end-uses was a separate operation; hence, capital-output ratios were used to derive the volume of investment, rather than the other way round. To project the use of resources, government consumption, fixed investment, inventories and the export surplus were estimated independently, and private consumption obtained as a residual. The subgroups of private consumption were estimated on the basis of demand elasticities, with a more complicated procedure taking account of existing stocks in the case of consumers durables.

The base year for the projections is 1955. The early base year is accounted for by the fact that, when the study was started in 1957, it was the latest year for which reasonably complete and final data were available.

For the 15-year period, the study arrives at an increase in the potential GNP for Western Europe of just under 55 per cent, equivalent to an annual growth rate of slightly less than 3 per cent. Receiving the volume in 1961, the first thing one is likely to do is to compare the projected growth rate with the actual experience for the first third of the projection, namely 1955-60. As the recorded growth rate was 4.2 per cent for these first five years, it is apparent that the rate of growth projected was a conservative one, and that the GNP potential by 1970 will be substantially higher than 55 per cent above the base year. If a constant rate of growth is assumed, the study's implicit figure for 1965 was nearly reached in 1960, while the growth rate needed in the present decade to achieve the 1970 potential is only 2.3 per cent a year.¹

It is a mistake to be put off by this comparison of the past, however, or to jump to the conclusion that the study is not revealing with respect to probable developments in the 1960's. For one must distinguish between the mechanics of the projections and their substance. I imagine that the calculation of the basic projections was finished in the course of 1957, and that the volume went to press before data for 1959 was reasonably complete. In 1957 the

¹ I have here allowed for the difference between the latest O.E.C.D. and the study's base year statistics.

projections might have seemed a bit conservative to some students of the European economy, but they would not have seemed unreasonable. I don't know anyone who was not surprised by the expansion of the GNP in the "recession year" of 1958; nor did anyone anticipate the size of the upsurge of the economy in 1959, and particularly in 1960, which started from a position of very low unemployment for most of the countries. Hence, one might say that the projections for the first five years were *dépassées par les événements*. This was a risk that had to be taken. The only conclusion to be drawn for future studies of this kind is that it might be better to separate the projections from the other large body of material and analysis in the volume, but to do them at the last possible moment, and to publish them quickly.

It is desirable, therefore, to let bygones be bygones, to move the base year up to 1960, and to see what the projections tell us about the outlook for the present decade. On the basis of the projected growth rate of almost 3 per cent the potential GNP for Western Europe will increase by one-third from 1960 to 1970. Here, one is confronted with the target of a 50 per cent increase in GNP for this ten-year period set by the Ministerial Council of the O.E.C.D. in November 1961. It implies an annual growth rate of 4.1 per cent. This goal covers the member countries as a group, including the United States with its heavy weight in the aggregate; but one may assume that Western Europe is expected to do its share in achieving the target.

As the difference between 3 per cent and 4.1 per cent a year is substantial, one may ask which rate of growth is likely to be more nearly borne out as the years pass. There is room for different opinions on the matter but I cast my vote with the Ministers. To bypass the many details involved in the estimates, I may support my preference by considering the prospects for the groups of industrial countries in Western Europe whose performance will determine the outcome.

The countries of the Six and Austria had an average growth rate of just under 5 per cent from 1955 to 1960. While it seems certain that the rate will be lower over the 1960's, it is still likely to exceed the Ministers' target. The past high growth rates for Germany, Austria and even Italy seem sure to be lower; however, Belgium should have an increased growth rate when the adjustment to the loss of the Congo has been made, and even France may average somewhat higher than the 4.2 per cent of 1955-60, which reflected the long pause as inflation was stopped and the franc stabilized.

The Scandinavian countries and Switzerland can be expected to have a lower growth rate also. It was 3.9 per cent in the 1955-60 period but Denmark has had a rather high rate, somewhat making up for an extended period of stagnation before 1956, while Switzerland is not likely to be able to continue the heavy importation of manpower which contributed to its past high rate of growth.

Finally, there is the United Kingdom, where the growth rate of 2.4 per cent per year has been low. The major obstacle to faster growth has been frequent balance-of-payments difficulties, which have required the authorities to maintain a restraining policy a good bit of the time. The authorities are trying to overcome this problem and I find it hard to believe that they will not meet

with some measure of success in the present decade, thereby making a higher growth rate almost inevitable. The United Kingdom itself does not have to reach the Ministerial target, which would be unlikely in view of the small proportion of unemployment at the beginning of the decade and the slow rate of growth in the labor force. The over-all target could still be met by the Six remaining above the target rate.

The target is by no means an easy one for Europe, as the increase of labor input will be small. But after the experience of the late 1950's, it does seem that the growth rate projected in the Dewhurst study is conservative. For the latter to prevail, I think some combination of the following conditions would be necessary: (1) failure of the United Kingdom to overcome its difficulties; (2) a sharp decline in the rate of productivity increase in the Continental countries from a fall in their external surplus (assuming total demand to be maintained); (3) failure of the Continental countries to maintain real demand at a stimulating level as the external surplus and the pent-up demand in a few sectors taper off. Any of these conditions is possible and each user of the projections must form his own ideas of the probabilities. I am, of course, excluding possible adverse political developments, which are excluded also by the assumptions of the study.

As to the projections of the uses of resources, there is little that needs to be said, except that it is again helpful to move the base year up to 1960. The growth rates for the various final uses of output are good working hypotheses, to be checked against the actual performance of the economy from year to year. If one is more optimistic than the study about the growth of the economic potential, this optimism must, of course, be reflected in the categories of final output. In that case it would be necessary to allow a more than proportional rise in the growth rate for fixed investment, other than housing, and probably also for consumers durables, particularly automobiles. It should be added, however, that there are widely different views about the probable growth of the automobile stock in the course of the 1960's.

I may conclude by shifting from the future to the past so as to comment briefly on the explanation of Europe's prolonged postwar boom that is given in the final pages of the first chapter. It is said that the boom was based fundamentally on great capital expansion and a vast demand for consumers durable goods, and the importance of government policy with respect to the former is emphasized. I believe that the stimulus from a buoyant export demand must be given at least equal importance with these two factors. While this is mentioned later, the key role of Europe's competitiveness in exports is not made clear; nor is it stressed that the countries which lacked this stimulus for longer or shorter periods failed to boom.

I believe also that the emphasis put upon "inflation-prone governments" is misleading from an analytical standpoint. The implication seems to be that Western Europe was continuously under the pressure of excessive demand. It must be recognized, however, that the rise in prices was partly an adjustment to suppressed inflation in the years preceding the 1950's, obviously the case with respect to the relaxation of rent controls and the removal of various consumption subsidies; that the rise of costs and prices for the

countries with a balance-of-payments surplus was in part an adjustment to the external surplus, even without there being excess demand; and that in some countries wage-cost inflation was a factor of considerable importance. At the same time, I agree fully with the author that the goal of full employment has been actively pursued.

These, however, are minor amendments to this broad and rewarding study of the European economy.

MILTON GILBERT

Bank for International Settlements
Basle, Switzerland

American Capital and Canadian Resources. By HUGH G. H. AITKEN. Cambridge: Harvard University Press, 1961. Pp. xii, 217. \$5.00.

This book is a review of the growing integration of the economies of the United States and Canada. The dilemma which this integration poses for Canada is described by the author as follows:

Every economic inducement, every opportunity for economic development impels Canada to accede to the continental pressures that now impinge on her. Every memory of historical tradition, every hope for the future preservation of national identity impels her to resist them. (P. 16.)

After an introductory chapter, the author reviews the facts of capital investment in Canada in a chapter studded with statistics gathered from well-known sources. This material will be very familiar to members of the profession in Canada and to many others, but will perhaps be less familiar to American readers. There follows a discussion of "the United States and the new staples" in which the familiar theme of American interest and investment in Canadian resources of raw materials is developed. A Canadian reader will be convinced by the time he reaches the end of this discussion that the book must have been written for non-Canadians. The discussion is competent and illuminating but does not add to the exposition or the insights offered in the publications of the Royal Commission on Canada's Economic Prospects or of the Canadian-American Committee.

The Canadian reaction to the historical trends is reviewed next. It is concluded that continental integration is not prejudicial to an increase in the diversity of the Canadian economy. It is concluded that the development of the Arctic is not a practical means of reducing dependence upon the United States, though in the last decade Canadian interest in her northland has increased. The important topic in this chapter is the Canadian worry over loss of national identity. The author finds it difficult to enumerate the respects in which Canadians enjoy separate identity; he stresses however that Canadians think they have it and that they wish to protect and develop it. "It is to preserve these possibilities of difference, rather than any manifest differences already existing, that Canadians feel compelled to resist absorption by the United States" (p. 151).

In the final chapter, the author speculates about the attitudes in Canada and the United States to the idea of a Canada-U.S. free trade area. He examines the contribution to continental integration of arrangements for the

defense of the two countries. He points to the inevitability of resistance from the provinces (whose revenues derive directly, in significant measure, from the exploitation of their natural resources) to any national policy of opposition to the economic penetration of the United States in Canada. Concluding that there is an inevitability about continental integration, he proposes that "Canada's best defense of its identity lies not in a rejection of challenges from the outside but in an emphasis on the quality of its response" (p. 193). At this point the Canadian reader finally will decide the book was written particularly for him.

Canada is at a crucial point in her history. The European Economic Community and the impending admission of the United Kingdom to closer union with this Community presents Canada with grave choices. These developments also pose difficult choices for the United States. One might have hoped that rather more than casual allusion to this critical policy choice would have been made in the book. Or, if the author chose not to deal specifically with current policy issues, one would have thought that in this book, marked as it is by a strong historical sense and perspective, he would have commented upon the implications of continental integration for the traditional Canadian problem of achieving national unity in the face of domestic racial and cultural diversity.

Canals and American Economic Development. By CARTER GOODRICH, H. JEROME CRANMER, JULIUS RUBIN AND HARVEY H. SEGAL. New York: Columbia University Press, 1961. Pp. vi, 302. \$7.50.

The Enterprise of a Free People: Aspects of Economic Development in New York State During the Canal Period, 1792-1838. By NATHAN MILLER. Ithaca: Cornell University Press, 1962. Pp. xv, 293. \$6.00.

Current interest in economic development has stimulated scholars, and notably economic historians, to re-examine early American experience for insights that may prove relevant to other countries now in the first painful throes of development. Both of these studies are so motivated; together they provide a rich lode of data and analysis, some of which is relevant to the world problem of economic development.

While both books deal with the canal period, differences in scope and emphasis render them complementary rather than duplicative. Students of economic development will find both indispensable. Miller limits his research to the years 1792-1838; the Goodrich study extends to 1860, well into the railroad era. Miller's interest is confined to New York State and the Erie Canal, while Goodrich and associates range beyond the Erie to analyze Pennsylvania and New Jersey canals in detail and to give brief attention to Southern and Western canals. Miller's study is not strictly canal-centered; rather, it is broadly institutional, over one-half the space being devoted to the financial and developmental operations of the Erie Canal Fund. Goodrich, on the contrary, deals more specifically with canals as such—their planning, construction, operation and economic impact. Both, however, are con-

cerned with the same basic questions: How did a people only recently emerged from colonialism and warfare, politically weak, desperately short of capital and deficient in technical knowledge manage to build these great works? How did this foundation investment in canals contribute to subsequent economic development?

By 1817 New York was not an "undeveloped area," in the pessimistic sense of current usage. Men had been dreaming of a great waterway to the West since 1724, and much exploring and planning had been done. The lure of the West, with its rich lands and unlimited opportunities, provided a powerful motivation, firing the imagination of the people and arousing their energies. Population, agriculture, industry, banking, trade and capital accumulation were all increasing rapidly; the acquisitive spirit of a burgeoning young capitalism was flourishing. In short, the economy was ready to explode if only the transportation bottleneck could be broken. Once the decision to build the Erie Canal was made the task proved easier than had been anticipated; domestic capital came forward, foreign capitalists, particularly English, were eager to invest in it, technical competence was discovered, and the Commissioners managed the enterprise with remarkable skill and integrity. A really "undeveloped" people could scarcely have done this.

This success, the authors agree, stemmed from the decision to make the Erie Canal a developmental, not an exploitative, project; it would be built by the State and operated for the public good, not alienated to some privileged corporation for private exploitation. Miller attributes this decision to the "abiding mercantilist tradition" then prevalent, to the fact that "the promotional and entrepreneurial role of the state was well established," and to the influence of Gallatin's Report of 1808 recommending public construction of canals. Goodrich and his associates, noting the same points, go on to emphasize the powerful influence of public hostility toward monopolies—"that prejudicial propensity to which incorporate bodies are subject."

New Jersey, however, in 1824 disregarded this admonition against monopoly and authorized two private canals. In doing so the legislature ignored popular protests, the advice of De Witt Clinton, and the recommendation of its own Canal Commissioners against "the pernicious, the deadly principle of confiding the vital interests of our country to the guardianship of men, whose only view can be pecuniary advantage to themselves." (Goodrich, p. 133). Both private canals involved political deals and special interest bargaining—the Morris Canal was combined with lucrative banking privileges and the Delaware-Raritan with a railroad charter. Goodrich and his associates think the Morris Canal had some temporary and local developmental effect, but that the Delaware-Raritan was almost entirely exploitative.

The canal experience of Pennsylvania was an exercise in frustration. Blocked off from the West by the Appalachians, Pennsylvania relied originally on its excellent turnpikes and gave little thought to canals. The success of the Erie Canal, however, threatened to divert Western trade from Philadelphia to New York, and this untoward prospect stimulated a belated and somewhat frenzied movement to build a mainline canal westward to

Pittsburgh with a portage railroad over the mountains. After a bitter debate between canal and railroad factions the first appropriation was made and construction started in 1826. This difficult project, including the portage railroad, was completed in 1834 at a cost of over \$12 million. In 1857 the Mainline was sold to the Pennsylvania Railroad for \$7.5 million. Although it contributed significantly to industrial development within the State, the Mainline was a failure in terms of its principal objective—to dominate East-West trade. It simply could not compete with the Erie Canal nor subsequently with the railroads. Long-range development would have been better served by an equivalent investment in railroads, notwithstanding their primitive technology, than in this uneconomic canal.

Miller shows how the Erie Canal Fund became a developmental bank, less by design than by force of circumstances. It mobilized domestic savings, attracted foreign capital, supported the banks by loans and diffusion of deposits, used debt management as an instrument of economic stabilization, and assisted the banks in meeting crises—Biddle's restriction of 1834, the great fire of 1835, the panic of 1837, and specie resumption in 1838. This use of public funds to aid private banks and to promote economic development through profit maximizing intermediaries was consistent with the mercantilist philosophy and the practical exigencies of the period.

Both studies demonstrate that investment in foundation capital is a prerequisite for economic development—a necessary first step to release the potential energy and creativity of developing economies. Both indicate that such investment can best be performed by the State. Neither author, however, ventures an opinion as to whether this early nineteenth century capitalist experience is relevant to the goals of undeveloped countries in the late twentieth century. The construction of canals was an integral feature of capitalist development; the State acted to assist a young, aggressive capitalism; the principal benefits accrued to bankers, merchants, investors, industrialists and land speculators. Will a system of economic development so motivated and directed prove acceptable or viable in the underdeveloped countries of our time, where social conditions and attitudes are so radically different? The presumption is strongly against it; the probability is that the State will not only provide the foundation investment but also control the direction of development.

HORACE M. GRAY

University of Illinois

The Emergence of a National Economy, 1775-1815. Volume 2, The Economic History of the United States. By CURTIS P. NETTELS. New York: Holt, Rinehart and Winston, Inc., 1962. Pp. xvi, 424. \$7.50.

This survey of American economic history between 1775 and 1815 constitutes volume two, and the eighth to appear, in the ten-volume series on *The Economic History of the United States*. The series is well planned, has high standards of workmanship, and has value for the research scholar and general reader alike. Each volume presents a well-digested and -documented

treatment of a significant period or episode in the nation's economic development. The present volume fully maintains these high standards and is compactly, judiciously, and interestingly written. The text (340 pages) is comprehensive, detailed, and heavily footnoted. There are an extensive bibliography (40 pages), an appendix (18 pages) containing statistics on population, public finance, wages, prices, manufacturing output, exports, imports, etc., and a detailed index (22 pages). Since this reference work constitutes an authoritative survey of economic change from 1775 to 1815, it provides a fine starting point for research concerning this period. Its author, professor of American history at Cornell University, is on the editorial board for this series; his related works include *George Washington and American Independence* and *The Roots of American Civilization: A History of American Colonial Life*.

This volume relates the events through which and manner in which the colonial economy of 1775 was transformed into the thriving, industrializing national economy of 1815. It sketches the character and extent of this transformation, as well as the political and economic innovations which prompted it. However, *what* happened receives greater stress than *why*; the treatment is more narrative than analytical, more descriptive than explanatory. The first two chapters describe in narrative fashion the economic impact of the American Revolution. The next two set forth postwar problems of foreign trade and domestic depression and the initial efforts to remedy them. Two others describe major economic changes produced by adoption of the Constitution and Federalist program. Three chapters depict the land policies, pioneering settlement, and agricultural development of the period 1775-1815, while two others trace the expansion of foreign trade. Three chapters describe innovations in transportation, manufacturing, and business organization. The last chapter narrates changes in national economic policy just before and during the War of 1812. Thus, the first six chapters and the concluding one treat in narrative form the unfolding relationships between political and economic changes, while eight intervening ones are topical treatments of particular sectors.

Nettels states in the preface that this was a period of political instability, "a time of revolution, war, and reconstruction," in which political and governmental changes transformed economic activity. He asserts that the role of government, including "political innovations and emerging institutions," must be stressed in this period since "the achieving of independence, the making of the Constitution, and the establishing of the federal government provided the legal foundations on which the structure of the economy of the United States has rested since 1789." Nettels is quite justified in proposing this emphasis, which may apply to later periods in only lesser degree. Indeed, his cut-off date of 1815 renders it difficult for him to articulate this emphasis. The political innovations, new policies, and evolving institutions of this period often reached fruition or had their major consequences long afterward. Consequently, his treatment of them, and especially of their consequences, remains incomplete as of 1815. Furthermore, his narrative and

descriptive method hardly allows him to analyze or interpret their effects and significance. The narrative approach seemingly does not facilitate historical explanation or analysis in cause-and-effect terms.

His obligation to cover myriad facets and details, reflecting the huge literature which he examined, causes Nettels to deal sketchily with such issues as Beard's economic interpretation of the Constitution, the central-bank function of the Bank of the United States, and the differing viewpoints of Hamiltonians and Jeffersonians. He does not highlight issues of interpretation, controversies in the literature, or major generalizations. Although he stresses emerging institutions and the role of government in the preface, his reader must do much inferring and generalizing to bring them into perspective and assess their long-run significance. As regards the legal foundations of capitalism, he barely mentions patent laws, bankruptcy laws, enforcement of contracts, legal aspects of slavery, and the place of the courts in protecting property rights. With respect to the role of government in promoting economic development, he only briefly notes the Northwest Ordinance, Louisiana Purchase, Lewis and Clark Expedition, Cumberland Road, and Gallatin's plan for internal improvements—without discussing early government interest in science, engineering, a proposed national university, and a coast survey or its activities fostering new territories and states, western exploration, engineering education, coastal fortifications, and collection of scientific data. Although it lacks comprehensive analysis of evolving institutions and of government's promotional role in this period, this reference work amply provides the research basis for such inquiries.

FOREST G. HILL

The University of Texas

Soviet Industrialization, 1928-1952. By NAUM JASNY. Chicago: Chicago University Press, 1961. Pp. xviii, 467. \$10.00.

The senior Western student of the Soviet economy has made another important addition to a long and distinguished list of his writings. *Soviet Industrialization, 1928-1952* is broader in scope than anything Dr. Jasny has produced thus far. It purports to cover all major aspects of the Soviet economy during the Stalin era, and to provide interpretive analysis of the developments under review with his own supporting statistical measurements. The task is nothing less than Herculean, particularly when it is remembered that Jasny is now in his late seventies and (to put it in his own words) "has only his pencil as an assistant." What is astonishing, in view of all this, is not the extent of inevitable omissions and the area of disagreement, but the degree of solid accomplishment.

Jasny sees no merit in subdividing the Stalinist era by the successive Five-Year Plans as it is usually done by Soviet writers. He offers instead the following periods: the "warming up" (1928 till the fall of 1929), the "all-out drive" (1929-1933), the "three 'good' years" (1934-1936), the "purge era" (1937-1940), and the postwar period, labelled somewhat jauntily "Stalin has everything his way." (The war years are omitted.) The major part of his narrative is organized in accordance with this scheme. It is

preceded by two introductory chapters, summarizing the main conclusions of the book and giving a thumbnail sketch of the developments of the first post-revolutionary decade. A brief "postscript" deals with the events of the post-Stalin era. In addition, there are two statistical appendices, and a note containing a moving tribute to Vladimir Groman, one of the leading non-Communists in the councils of the early Gosplan and the chief defendant in the notorious "Menshevik trial" of 1931.

The rich fare provided in the volume defies adequate summary within a short space; only a few highlights are possible. This reviewer found the description of the "all-out drive" of the early 'thirties particularly rewarding. The monumental distortions and imbalances in the economic system during these years are presented more fully and forcefully than in any other source he knows, and the table showing huge divergencies between some of the key targets of the initial draft of the second Five-Year Plan and the actual fulfillment vividly illustrates what Jasny calls "bacchanalian planning." Yet the author very properly cautions against premature conclusions when he comments: "it seems certain that the blunders of the *All-out Drive* are not going to be repeated in full strength" (p. 29). The discussion of the agricultural situation contains much that is new in sections dealing with the postwar period and displays throughout the incisiveness and skill which one has come to expect from the author of the pathbreaking *Socialized Agriculture of the USSR*. It was in this field, incidentally, that Jasny performed his major statistical *tour de force* when he adjusted sharply downward the figures of the official Soviet grain series based on the so-called "biological yield"; his results turned out to be very close to the figures of the "barn yield" series released by the Soviet authorities seven years later. Speaking of statistics, Jasny is undoubtedly on the right track when he castigates the official Soviet fixed investment series and specifically, the part pertaining to the postwar period. It is indeed hard to reconcile the figure for the volume of fixed investment in 1945 which shows a decline of only 9 per cent from the 1940 level with everything we know about the very drastic drop in the output of constructional material and of important categories of civilian machinebuilding as a result of the war; and it could be easily shown that a downward revision in the investment figure of 1945 would require a corresponding adjustment in the investment figures for later years as well. Yet with regard to the last period of the Stalin rule, the profound scepticism toward the official statistics and equally profound distaste for the policies described do not prevent Jasny from recognizing the achievements in terms of growth. After citing his own estimates of Soviet economic expansion during the seven postwar years (more than 50 per cent increase over the level of 1940, and more than 100 per cent above 1945) he concludes: "All in all, a favorable picture, except for the price of this growth. . . . It is left to the reader to appraise this price as compared with the attainments" (p. 430).

These and many other instances illustrate the qualities which have been generally recognized by students of Jasny's earlier writings: a strong sense for facts, an uncanny ability to uncover weaknesses and incongruities in economic reality and in its statistical portrayal without losing perspective

and forgetting about elements of strength, and, last but not least, boundless energy and enthusiasm. Yet while these admirable traits of the "Jasny approach" are clearly present in *Soviet Industrialization*, so are some of its controversial aspects. The computations of Soviet national income put forward in Jasny's earlier writings have been repeatedly criticized for his incomplete description of the underlying derivations, for the unrepresentative character of his price data and for his excessive reliance on "rule of thumb." More specifically, it was argued that Jasny's price data were particularly deficient in the area of newest and fastest growing output categories such as machinery, and that this circumstance, together with the inclination to use the 1928 outputs as weights for price indices was bound to result in excessively high deflators and thus to understate the rate of growth. No doubt, most of these shortcomings are due, in large part, to superhuman difficulties of working alone in a vast and immensely complex field; but this, unfortunately, does not make them less real, and Jasny's present volume will not dispel the doubts. (Actually, his revised national income series, based on "real 1926-27 prices" shows a somewhat lower rate of growth for the prewar period than the original version. On the other hand, it should be noted that Jasny's index for the postwar period diverges much less from the official Soviet index and from other Western estimates than his prewar figures, possibly because a more stable composition of Soviet output during the postwar years resulted in smaller sensitiveness of the production index to difference in weights.)

In short, it is difficult to escape the conclusion that a valiant attempt to adjust downward the inflated figures of Soviet statistics has been, in this particular case, carried too far. But also outside the murky area of index numbers there are points in Jasny's analysis which one would like to question; in this reviewer's view, they stem almost invariably from a tendency to overstate a good case. A few examples are in order. Jasny's description of the "all-out drive" is, to repeat, highly effective in demonstrating massive irrationalities of the official policy at that time; yet the evidence which is entirely adequate for this purpose, is not sufficient to sustain the proposition that "real national income was actually declining during the greater part of the All-out Drive" (p. 16). Similarly, Jasny's strictures against the inefficiency of Soviet investment during the same period would be more convincing and less vulnerable to attack if he had explicitly acknowledged that many investment projects launched under the first Five-Year Plan could not conceivably have been completed within the time horizon of this plan even under the best of circumstances, and that for some of them the long "period of waiting" would be justified by their (properly discounted) returns. With regard to the 1937-1940 period, Jasny would have been right in arguing that the purges of the late 'thirties must have contributed to the significant slackening in the pace of Soviet economic growth during these years. But it is difficult to understand his refusal to admit that the drastic shift toward military preparedness must have also had something to do with it: wasn't a slash in the volume of investment going to iron and steel industries by nearly two-thirds which paralleled a rapid increase in the share of munitions in the steel consumption from 1934 to 1938, bound to result

in a lower rate of growth even if there had been no purge? Lastly Jasny deserves our gratitude for reminding us of Groman's leading role in the work on the "balance of national economy" which was published in the mid-'twenties. However, it is an exaggeration to argue, as he does, that the checkerboard table of this balance embodies "the idea of input-output analysis" (p. 441). In fact, it represents merely a modest step beyond the constructs of Quesnay and Marx, but contains no trace of the concepts of direct and indirect input coefficients or of the underlying computational and analytical techniques which constitute the heart of Professor Leontief's method.

Yet it would be utterly unfair to conclude on this note of criticism. Like all scholarly works of enduring value, Naum Jasny's writings enlighten even when they provoke disagreement, and *Soviet Industrialization* is no exception. He has put us in his debt once again; and all his friends will undoubtedly share this reviewer's fervent hope that he will keep enlarging this debt for many more years.

ALEXANDER ERLICH

Columbia University

The Soviet Economy: An Introduction. By ALEC NOVE. New York: Frederick A. Praeger, 1961. Pp. 328. Clothbound and paperback editions.

This is an excellent book—a model introduction to a complex subject. My only serious complaint is that the book is too short. Mr. Nove has a very succinct style and packs a tremendous amount of information and analysis into a page. The result is that beginning students may find the book demands more concentrated attention than they expect to give to a book with the disarming subtitle, "An Introduction." If they persevere, however, they will find their persistence well rewarded. Their instructors can refer them to the book with confidence that Nove writes with learning, clarity, and careful judgment in controversial areas.

The book is divided into three Parts, "Structure," "Problems," and "Concepts and Ideas." The first Part has chapters on "Productive Enterprises," "Administration, Planning, Policy Decision," "Public Finance and Credit," and "Wages and Prices." These are primarily descriptive and very well done. It is a little disconcerting at first to have to search through several chapters to find what one wants on, say, agriculture; but Nove's scheme of organization is perhaps more meaningful to the economist than is the usual topical institutional approach. This Part would have been improved, however, by the inclusion of a chapter on foreign trade (in place of the few pages following p. 189) and by a chapter on health, education, and recreational activities. If we are interested in the inter-country comparison of real wages, it is desirable to make explicit the importance in the Soviet world of this collectively provided part of real wage income.

Although a little historical material is woven into the account, personally I have found economics students so ignorant of Russian economic and social developments before the Revolution that it is necessary to fill them in with the background of the continuing agrarian problem, forced draft industrialization, and the role of the state in economic development. Otherwise,

they tend to regard as being exclusively Communist, phenomena which really are traditionally Russian. Likewise, because of student ignorance, I have found it essential to give a brief sketch of Russian economic geography. Nove may be more fortunate with his students at the London School of Economics; but for American colleges and universities introductory chapters on Russian economic development before the Revolution and on Russian economic geography would greatly improve the book. In my courses, I shall probably supplement the book by assigning readings in Hugh Seton-Watson's, *The Decline of Imperial Russia, 1855-1914*, which gives just the background needed to supplement Nove's book.

Although the statistical tables are well chosen, I wish there were more of them.

It is in "Part II: Problems" ("Micro-Economic Problems," "Planning and Investment," "The Pricing of Factors of Production," and "Trends Towards Reform") and "Part III: Concepts and Ideas" ("Some Basic Concepts of Soviet Economics," "Soviet Economics and Economic Laws," and "Assessment") that Nove is truly excellent and goes beyond the normal textbook in this field. His distillation and presentation of the complex debates within the Soviet Union about economic theory might profitably be assigned as supplementary reading in intermediate theory courses.

There is a very useful short bibliography at the end, a subject index, and an index of names.

This short but scholarly book can be strongly recommended as a basic text (if supplementary material is assigned) for courses in the Soviet economy or for courses on comparative economic systems in which the emphasis is on the U.S.S.R. It is refreshing to find an author who can say so much that is worth while in such a short space and can say it in so literate a style.

JACK TAYLOR

Rochester, New York

Méthodes de prévision du développement économique à long terme. Report of a group of experts. Informations Statistiques, No. 6. Brussels: Stat. Office of the European Communities, 1960. Pp. 172. Bfr. 250.

This highly specialized report by a panel of seven European experts was written at the request of the authorities of the European Coal and Steel Community. The product of the joint effort of these experts is a set of uniform techniques and guidelines designed for economic planners in the countries comprising the European Economic Community. In other words, this study is strictly for the specialist.

The authors rely predominantly on econometric models. In their view (p. 537) the over-all, rather than the detailed, approach is more suitable for economic programming, and they devote much space to an elaboration of an over-all production model, to methods of estimating total demand, and to the reconciliation of the projections to be obtained by these two approaches.

The production model chosen by the authors is the well-known, and recently again popular, Cobb-Douglas production function of the type $Y =$

$\beta K^\lambda L^\mu$, where β rises exponentially over time and $\lambda + \mu = 1$. Inasmuch as this production function assumes an unchanged economic structure, high elasticity of substitution between factors, and constant returns to scale, the question of its applicability to the future conditions in the EEC may be raised. Since technological progress is generally recognized as an autonomous factor in the growth process, it appears that the authors have postulated that the Common Market will not affect technological progress greatly.

While the stress placed on the supply side is quite understandable in a period of rapid economic growth in Western Europe, typified by full employment and inflationary pressures, the authors are definitely correct in rejecting the notion that it is supply which sets the limits to economic growth and thus in stressing also the main elements on the much more elusive demand side. In doing so, they seem to be guided by similar thinking so eloquently expressed recently by Professor Hollis Chenery when he wrote: "Since market forces cannot be relied on to balance supply and demand under conditions of . . . accelerated growth, a principal concern of development policy is to ensure the consistency of production levels with commodity demands and factor supplies" (*Am. Econ. Rev.*, March 1961, p. 48). The reconciliation of these two projections has definite merits since it permits a more careful insight into the problems of economic capacity, the level of employment, etc. Thus, both approaches could provide an indication of the magnitudes of the adjustments that will be required. On the other hand, the question as to what the residuals represent, that is, whether they are systematic errors or only temporary inequalities, is left to the practitioners to decide.

The specialist in the field will find only little that is original and new in this study. In addition, in reading the French version he will soon discover that "prévision" means programming, or projection, or forecasting; but he will be compensated inasmuch as the authors proceed slowly, carefully, perhaps at times too meticulously. The 53-page-long statistical appendix may be of some interest; it does not seem, however, to be well incorporated into the text.

Finally, in reading this report, one often wonders whether the authors would recommend in the economically less developed countries the same techniques they recommend for the advanced European countries. This issue was left out entirely. Of course, this was outside the immediate scope of the authors' assignment and one cannot criticize them on this score.

STEPHEN SPIEGELGLAS

Boston University

Development of the Emerging Countries: An Agenda for Research. By R. E. ASHER, E. E. HAGEN, A. O. HIRSCHMAN, G. COLM, T. GEIGER, A. T. MOSHER, R. S. ECKAUS, M. J. BOWMAN, C. A. ANDERSON, AND H. WRIGGINS. Washington: The Brookings Institution, 1962. Pp. xi, 239. \$3.75; paper, \$2.75.

If anyone still wonders why research on development processes is attracting many able scholars, he will find an answer in this conference volume. It reveals exciting frontiers of current investigation where each skill of the

social scientist is useful, but all have something to learn beyond their usual disciplines. There are six papers, plus one comment and a concluding review, selectively harvested from a meeting of 75 specialists in May, 1961. The participants were asked how research resources should be spent by the Agency for International Development, the foundations, and each other. The authors have prefaced their essays by stating the leading hypotheses in their fields having relevance to international assistance. It is the further testing, refinement, and use of these hypotheses in studying particular problems which make up the "agenda for research." Several authors state pointedly that aid programs could better take into account what we already know about development.

Everett Hagen presents as the framework for analyzing economic and political change his system of interacting "technical-economic" and other social variables. The exposition utilizes new material showing a positive correlation between the level of economic development and the "competitiveness" of the political structure. He explains the role of "creativity" in adaptive innovation, and suggests that certain present-day response patterns were produced by past colonial experience. From these considerations he derives several sensible precepts to guide U.S. policy. He advises that future research employ perceptive skills that examine problems in more than their material dimensions.

Commenting on the "framework" problem, Albert Hirschman urges Americans (especially J. K. Galbraith) to be less concerned about fulfilling prior conditions for making aid effective and to notice that development occurs "invariably in the absence of one or several of these 'required' components or preconditions" (p. 41). It is these "new or inverted sequences" which research must explain and which aid may promote.

Hirschman suggests, too, that the Hagen and W. W. Rostow explanations of growth are logically the same, because they both stipulate sets of preconditions to be satisfied at a certain stage. But there is, in the reviewer's opinion, a very important difference between the Hagen and Rostow models of change. Hagen gives several informal indications that he is not using a stage theory, including the statement that in "almost all underdeveloped countries . . . conditions are somewhat conducive to growth, and somewhat deterrent" (p. 26). In order to give precise meaning to the time-ordering concepts of "preconditions" or "stages," it would be necessary to confine changes in some subsets of the variables (i.e., assign certain distinctive types of events) wholly to particular historical periods. Hagen appears to have decided against such restrictions. Instead, he envisages continuing interdependent change, even in that part of his model which involves the production of "creative" persons. In Hagen's book, *On The Theory of Social Change* (Homewood, Ill., 1962), published subsequently, his differences with Rostow are made explicit (pp. 514-22).

Gerhard Colm and Theodore Geiger describe a procedure of "pragmatic planning" which corresponds well with our limited knowledge of how planning is being done. It provides a basis for utilizing together tools which have at times competed against each other for exclusive authority, such as

mathematical programming, project appraisals, and judgment. Because we have less analytical knowledge of planning experience than of theoretical precepts, research should now stress the former. For a perspective on development planning techniques, this essay is a good reading assignment at the graduate level.

Arthur Mosher writes about research on rural problems. He asked colleagues in his field to identify and rank research needs in relation to the operation of technical assistance programs. Their answers and Mosher's own perceptions are combined in an outstanding survey suggesting many specific research hypotheses. He recommends that research activity be fostered abroad because it is a process which itself teaches and develops people. The role of research as a development process was stressed by several other authors, too.

R. S. Eckaus, writing on technological change, is impressed by our lack of quantitative knowledge of technological relationships, by which he means the description of inputs associated with particular outputs. He advocates the massive collection of such data at a micro level, with reference both to current and possible technologies. With such information and a refined theory of technological choice in hand, aid programs could supply answers to questions that they now only ask. The Eckaus assistance process is to supply knowledge from abroad and to use foreign consultants when problems arise in the field. It contrasts with the concern for domesticating learning processes within the aided populations which most of the other authors express.

Mary Jean Bowman and Arnold Anderson write about the role of education in growth diffusion processes. Because change initially is localized and unbalanced, the problem is to facilitate its diffusion and multiplication.

Howard Wiggins examines the relationship of foreign assistance to political development. Assistance programs intrude on the complex process of political change, notwithstanding the myth of "non-intervention." He indicates some of the many questions we need to answer to become aware of the full consequences of aid programs.

Robert Asher edited the volume and writes a brief concluding review. Altogether, these essays are an excellent and economical opportunity for professional economists to acquaint themselves with some of the issues and methodologies that now occupy social scientists in the development field.

FREDERIC C. SHORTER

Princeton University

The Statistical System of Communist China. By CHOH-MING LI. Berkeley and Los Angeles: University of California Press, 1962. Pp. x, 174. \$4.00.

Among the many basic problems of research on Communist China, perhaps none is more controversial and stands in more urgent need of a thorough investigation than that of the reliability of official statistics. The book under review is the first serious attempt to tackle this complicated problem through a study of the development and inner workings of the statistical system.

The study falls into three parts, each dealing with the development of

the state bureau and its impact on the quality of statistics in 1952-57, 1958, and 1959-60, respectively. Out of a massive collection of fragmentary information, the author painstakingly pieces together a coherent and fascinating story of the continuous struggle of the state bureau to build up an independent statistical service amidst many difficulties, not the least of which is the constant resistance from the "business affairs departments," the Planning Commission, and the local cadres. The period 1952-57 witnessed the gradual development of the state bureau into a relatively workable system, only to be shattered by the abusive use of statistics by local party members during the big-leap movement in 1958; eventually the system emerged more penetrating and effective than before, but subject to tighter political controls. The study, however, is much more than a history of the state bureau. Changes in the comprehensiveness and accuracy of statistics which accompanied changes in sources of information, methods of compilation, effectiveness of quality control, and quality and morale of the personnel, are all carefully examined. Very briefly, the broad conclusions are that, despite some improvements, the quality of official statistics in 1952-57 was rather poor, became much worse in 1958, and remained in an unsatisfactory and uncertain state thereafter. On the relative quality of different types of statistics, the author accepts the Communists' own ranking.

Most readers will be impressed by the author's mastery of the art of uncovering the hidden, by his penetrating analysis and lucid presentation. His keen observations on the limitations of the quality control devices, on the question of barn versus biological yield, and on the implications of the "partisanship principle" are examples. The chapters on the 1958 big-leap episode are especially incisive. Here the reader is given an excellent account of how and why the statistical fiasco took place. The discussions on the shortage of trained statisticians, lack of standardization of statistical schedules, and inadequate supply of measuring equipment are certainly worthy of the serious attention of policy makers in underdeveloped countries.

However, the reader whose primary concern is the usability of official statistics will perhaps find the treatment of many key problems inadequate and the conclusions at times so sweeping as to raise rather than solve problems. The following are some examples.

The author raises the question of double-bookkeeping on page 60, but does not refer to it again until the last page of the book, where he concludes that "if it is true that only statistics of achievements are published while those reflecting difficulties and problems are either withheld or not collected at all, then there are not likely to be two sets of national statistics, one for planning and the other for propaganda" (p. 149). It may be true that only a single set of books is being kept by the state bureau, but the conclusion would perhaps require something more convincing than a statement based on a priori reasoning. For while double-bookkeeping and the withholding of information are both tools of propaganda, the use of one does not necessarily preclude the use of the other. The fact that more than one account is prepared by the lower echelons (pp. 85, 119, 120 and 134) certainly calls for closer examination of the problem rather than for a single, highly speculative observation.

Professor Li's study is primarily concerned with statistical errors that are introduced in the course of the flow of the statistics from the primary establishments or basic administrative units to the center. Virtually nothing is said about methodological deficiencies in technical processing of the data at the center, and errors at the primary level are touched upon only incidentally. It is understandable why the technical biases are left out of the picture, but the lack of a systematic and thorough analysis of possible errors at the primary level seems to this reviewer a major omission, for two principal reasons. First, the study thereby leaves open many questions bearing directly on the reliability of statistics. For example, are there any write-ups, write-downs, or other unintentional errors at the factories or cooperatives? If distortions are deliberate, who falsifies and why? To be sure, some such errors are mentioned, but they present an incomplete picture. For example, the overreporting of output by factories noted by the author (p. 44) is but one form of falsification. At times, some underreport their output, presumably to show a more dramatic increase in the next period. Similarly, some agricultural cooperatives distort their reports in different directions for different motives, overreporting the cultivated area to obtain larger quantities of seed, and underreporting the same to reduce the tax quota. Other distortions, such as inflation of basic construction statistics, or fertilizer accumulation reports that conceal product adulteration, have not been considered. In sum, the study fails to bring out the nature and extent of the built-in institutional biases characteristic of Soviet-type economies, where rewards to the individual are often directly linked to his statistical showing.

Furthermore, the rather narrow scope of inquiry limits seriously the possibility of appraising the over-all quality of the statistics. Clearly, organizational improvement is a necessary but not sufficient condition for improvement in the quality of statistics. Thus the breakdown of the system in 1958 inevitably led to deterioration of quality, and here the author is in a position to, and does indeed, make some very specific comments. But the resurgence since 1958 provides no assurance of quality improvement, not merely because of possible subjective intervention by party committees (as the author correctly points out), but also because of the possibility of errors originating at the primary establishments or caused by methodological deficiencies.

In discussing the quality of agricultural statistics in 1952-57, the author contends that those of 1955 were probably the least unsatisfactory (p. 58). As his evidence he cites three reasons: the establishment, for the first time in 1955, of statistical committees at the hsien level or below; the editing of reports at different levels of the local government to balance the tendency of the production bureau to inflate the figures against that of the tax collection and internal trade bureaus to do the opposite; and an inclination among the local leadership to inflate figures in 1956-57. The author does not explain how the hsien committees could have contributed substantially to the quality of agricultural statistics in 1955 as compared to the pre-1955 data. In fact, it is doubtful whether they actually did. For the major method of investigation was the same model survey used in 1953-54, the models were primarily the same mutual aid teams and cooperatives, and the persons in

charge of reporting were the same local cadres (pp. 30-31). The two arguments for the assertion that quality was higher in 1955 than in 1956-57 are also open to question. The observation that there were two conflicting biases is based on a single sample in a particular area in Hopei (p. 29). Even if it applied to the situation in general, it is by no means certain that the biases could be canceled out through editing. In fact, the author himself notes that such editing was often arbitrary (pp. 29, 43). As for the third observation, no specific evidence is given.

But granted that all of Li's observations are valid, two serious doubts remain. First, the inference that between 1949-57 agricultural statistics in 1955 were best (p. 58) is clearly inconsistent with another statement that from 1954 onward, to the end of 1957, the quality of official statistics improved (p. 63). Second, the inference itself seems hardly justified by the author's own arguments because, as noted above, errors other than those resulting from the collecting and editing by the cadres have not been taken into consideration, e.g., the widespread underreporting of output and cultivated area by the cooperatives in 1956-57 (pp. 32-33). The conclusion on page 58, therefore, requires either a *ceteris paribus* reasoning or the assumption that, on balance, the upward bias in editing is overwhelmingly strong, which in turn would need concrete supporting evidence.

The book includes a useful bibliography on the subject. But, surprisingly, it leaves out such items as the several handbooks for statistical work available in addition to that for agriculture. Also, the press communiqué on economic achievements in 1959 is conspicuously absent, although the data from this and other sources would be useful in filling some of the blanks in Table 2 (p. 90) and in strengthening certain arguments in the text. The reader may also miss a flow chart showing who collects what from whom and how, an aspect on which information is unfortunately scattered and incomplete. For instance, the observation that annual schedules collected from state, joint, and cooperative enterprises constitute a complete count (p. 37) is interesting for its implication about statistical coverage, but not very enlightening since it is not made clear what specific series (other than some industrial indicators) are included in the regular schedules.

Despite these limitations, this highly readable volume will be extremely valuable to all students of Communist China, not only for its many insights into the statistical system but also for the clear, unmistakable emphasis on the need for caution in the use of official statistics. Indeed, it will compel the reader to ponder over such statements as those by Joan Robinson and Sol Adler that "the Chinese are conservative rather than otherwise in their compilation of statistics for economic planning" and that (for 1958 and before) "grain production data represent not the biological crop (on the stalk) but the crop in the barn after it has been dried in the sun."¹

¹ Joan Robinson and Sol Adler, *China: An Economic Perspective*, The Fabian Society, London 1958, p. 2.

India's Economic Growth Processes, Problems and Policies. By J. K. SENGUPTA AND A. SEN. Calcutta: The Post-Graduate Book Mart, 1961. Pp. xvi, 260. Rs 15.00.

This wide-ranging collection of papers is divided as follows: Part I, "Growth in the Agricultural Sector"; Part II, "Growth in the Industrial Sector"; Part III, "Industrial Labour in a Growing Economy." The first part consists of three chapters by Mr. Sen while the second and third parts were authored by Mr. Sengupta. Topics include a spectrum of subjects, each of which could be better handled as a monograph. However, much useful information is compressed succinctly in each paper.

Sen's treatment of agriculture's production, productivity and prices reproduces the conventional governmental data and constructs original indices to highlight important phenomena. Thus an index of agricultural productivity derived by dividing the index of agricultural production by the index of area under cultivation shows that in spite of a substantial rise in output, the yield per sown acre has not changed much—even in the modern period of planning.

Linking up this conclusion with the question of why agricultural productivity should remain stagnant, the chapter on agricultural structure, seeks to demonstrate that the answer does not lie in changing insecure, small land holdings. In his policy chapter on tenancy, Sen points out that data from the United States and Japan suggest the explanation lies not in the conventional input of labor (which has fallen relatively) or capital (which has increased but slightly), but rather in improvements in the quality of resources employed; i.e., more investment in human resources and improved techniques. Since investment in human agents is not readily sellable to the rural people because immediate benefits are not apparent (wherein he says, lies the failure of community development), it is best to concentrate on changing the nature of nonhuman agents. Farm management assistance, "improved seeds, adequate fertilizers, water management, timely tillage and other practices will result in startling increases in output" (p. 57). Other conclusions such as allowing market forces freer play make good reading in the United States, but probably will have little effect in India.

The linkage and unity of thought manifested by Sen is not carried out in the second and third parts by Sengupta who has presented discrete essays on various aspects of planning, industrial productivity, location theory, problems of excess capacity, rationalization, industrial relations, wages and profit sharing. In spite of the absence of any summary package, the author formulates a good discussion of each topic and generates useful though sometimes hackneyed or dated insights.

Thus in the Mahalanobis planning critique, questions are raised for example, about the failure to specify sectoral capital output ratios (p. 82), the failure to subdivide the capital goods sector into subsections, as was the consumer sector, and the failure to guarantee greater utilization of manpower. This kind of critique has been heard before. Also of a familiar ring are dated discussions such as the size of the third plan. These last sections also suf-

fer from a compactness and heaviness of style, and the book as a whole is marred by numerous typographical errors which some old-fashioned proof-reading might have easily removed. In spite of such blemishes, the book seems to be a useful critical summary of important aspects of India's developing economy.

DANIEL L. SPENCER

Howard University

Formulating Industrial Development Programmes—with Special Reference to Asia and the Far East. Report by a Group of Experts. Development Programming Techniques, Series No. 2. Bangkok: U.N. Economic Commission for Asia and the Far East, 1961. Pp. xiii, 137. \$1.50.

The object of this study is to provide expert technical guidance to governments of the ECAFE region in the programming of development plans. The group of six experts, under the chairmanship of Hollis Chenery, of Stanford University and currently with the U. S. Agency for International Development, included a Soviet planner and produced a unanimous report.

The main theme of the report is the interrelation of analytical techniques, industrial structure and statistical data required for programming. The report is composed of three parts. The first part applies the conceptual framework developed in other studies to the three levels of analysis required for industrial programming; aggregate, sectoral and project. The analytical procedure is then used in the second part as a basis for evaluation of statistics available in the ECAFE region and for suggesting areas where improvement is most urgent. The last part reviews the industrial planning experience of the more advanced countries in the region in order to suggest procedures that may be useful to others.

Industrial planning seeks to allocate resources over time to achieve a set of specific social goals. The essentially static concept of optimum allocation of resources has to be married to the dynamic notion of growth. The technique of programming propounded in the study under review is that of activity analysis that attempts to go beyond the simple input-output matrix in order to reconcile feasibility with efficiency. Feasibility is tantamount to insuring that inputs will be consistent with levels of output derived from demand projections, and efficiency is assured by the use of the social productivity criterion, i.e., the social return on capital investment. The six experts are fully aware that in a dynamic setting efficiency of production changes over time, that external economies exist and that prices of inputs and outputs differ from opportunity costs. To deal with these difficulties the authors of the study introduce the concept of accounting prices and the notion of the iterative planning. Accounting price represents the opportunity cost of an input, or the loss to the economy that would result from a reduction of its supply by one unit. Inasmuch as the estimates of accounting prices can at best be only tentative they are subject to constant revision as industrial projects are considered and evaluated. The revision of accounting prices in turn modifies the calculations of industrial specialists and affects the decisions over specific projects.

It is a great merit of the report that theoretical assumptions are not set

out didactically and that the authors are constantly aware not only of imperfections of data but, perhaps more importantly, of the complexity of the decision process where qualitative, intangible, or political considerations may obscure the rationality of development programming. It is readily assented, for example, that project decisions may have to be modified by such considerations as self-sufficiency, the desire to help underdeveloped regions or the aim to propagate scarce skills. But the study points out that the programming technique is still superior to any other decision function in that it can be precise as to the cost of achieving alternative goals and so provide a basis for intelligent choice, even if the choice is to be made on grounds other than economic.

Another useful feature of the study is the suggestions it contains, at every level of analysis, of the ways to fill in the gaps in the requisite data which are bound to occur in most of the countries embarking on industrial planning. Thus, for example, at the aggregate level of analysis, projections of demand for a given output can, if necessary, be made by using the income elasticity coefficients borrowed from other countries and cited in the study.

In the same vein, techniques and procedures employed in programming are illustrated throughout by examples of actual work done in other countries. The examples most frequently used are taken from studies of Peru which while not in the ECAFE region possesses many of the structural characteristics found in the region.

It is regrettable, if unavoidable, that the study, which is admirable as a manual of industrial programming, is not self-sufficient but has to refer to other studies on development planning published by the United Nations. One would also like to see a more extended discussion of accounting prices and particularly some hypothetical illustrations of their computations and subsequent revision in the light of, say, development of new export outlets. But there can be little question that, at the very least, the study will serve as a powerful stimulant to planning and will cause a revision of many "intuitive" industrial priorities. Nor is the study itself, or the techniques it suggests, premature for the countries of the region. In India, for instance, at least one-third of total industrial output is destined for other producing sectors and other countries in the region show an even greater degree of complexity and interdependence among industrial sectors.

In fact, the timing of the publication of the study coincides with the announced change of emphasis in U.S. aid from a mere examination of individual projects to an evaluation of the total contribution to a country's development program. The technicians administering aid as well as those in the recipient countries will find the study of great practical value.

ALEK A. ROZENTAL

Agency for International Development

A Magyar mezőgazdaság termelés: korzetek. I. A szántóföldi növénytermelés korzetek. By DR. TIVADAR BERNAT AND DR. GYORGY ENYEDI. Budapest: Mezőgazdasági Kiado, 1961. Pp. v. 168. Ft. 120.00.

The title of this book may be translated as *The Production Regions of Hungarian Agriculture*. The subtitle I. *The Regions of Fieldhusbandry* in-

dicates the intention of the authors to write another volume, or volumes, on regions of other branches of Hungarian agriculture. The purpose of the study, as the authors state it in the Preface, is to attempt to define and analyze the existing (1954) production regions of Hungarian agriculture.

A special, practical reason for publishing the study, say the authors, is "to draw the attention of the planning authorities to the enormous possibilities which lie in the optimal placing of production, and in its geographical specialization, particularly during the rapid collectivization of Hungarian agriculture." The objective of the authors seems to be to rehabilitate the geographic division of labor in Hungarian agriculture which existed before the war. They spell this out in their critical words about the past: "Our agro-political actions, during the first five-year plan,¹ because of the lack of regional knowledge, determined the production purposes of the individual areas in a way that was contrary both to the natural conditions of production and to the interests of producers. The uniform production schemes not only reinforced the underdeveloped production structure of the past decades, but in some regions (onion-region of Mako, paprika-regions of Szeged and Kalocsa, etc.) even degenerated the recognized geographic specialization, weak as it was, because of the large emphasis on grains" (p. 14).

The authors go on to say that a large number of the producers, following the directives and aims of the five-year plan, were obliged to develop agricultural specialties, and to allocate resources, in ways which often led to a decline of the volume of products from a unit of land.

"The neglect of regional research and the underestimation of already existing modest achievements in the working out of regional economic plans resulted, in numerous regions, in the alteration of the production structure in the wrong direction. Because of this, and also because of the disregard of the law of value,² the formerly weakly developed regional division of labor did not, generally speaking, develop further during the first five-year plan. In certain regions it even withered away, causing great damage both to the producers and the people's economy.

"It is the task of the future, to renew and reinforce the regional specialization of agriculture concurrently with the increase of production and even in the interest of it" (p. 15).

The authors also suggest that scientifically defined agro-regions be the basis for the preparation of national development plans.

The method used by the authors for defining production regions of each major crop was to determine the ratio between the average yield of a township and that of the country as a whole. In the case of the complex regions of fieldhusbandry, the authors regarded the money value of production per unit of land as the most important indicator reflecting productivity and intensity of farming. Skillfully using these principles, the authors give a comprehensive analysis of Hungarian fieldhusbandry which is undoubtedly

¹ I.e., during the Rakosi-regime.

² Favored jargon for the practice of paying producers' prices at near cost of production level.

the best seen so far. Fifty maps and 100 tables supply a well-selected documentation to the narrative.

The Hungarian, and most other agricultures in Eastern Europe, have grave production problems for two reasons. The economies of the countries cannot afford to subsidize agriculture; therefore productivity is low. On the other hand political and not economic considerations play the primary role in forming agricultural policy. Geographic specialization of agriculture, as it came into existence historically, was a reflection of past socio-economic conditions. The last remnants of these conditions in Hungary had been destroyed by the total collectivization of agriculture, by the time this book was published. Although the effort of the authors to give sound principles for the development of agricultural regions is laudable and largely successful, the responsible authorities will hardly be in a position to pay too much attention to geographic niceties in the midst of a recently collectivized agriculture with problems comparable to those of colonizing the moon.

Economic Systems; Planning and Reform; Cooperation

The Economics of Socialism Reconsidered. By HENRY SMITH. London: Oxford University Press, 1962. Pp. x, 225. \$4.80.

Henry Smith (vice-principal of Ruskin College, Oxford) is an old Fabian socialist. "The subject of this book," he begins, "has been the main interest of all my adult life." However, its title may mislead. The book deals only briefly and incidentally with the constructive welfare economics of a socialist state, the subject of books with similar titles by Renard, Jevons, Hall, Dickinson, J. H. Smith, and this reviewer.

Chapters 2, 3, and 4 (80 pages) discuss neoclassical economics, Keynes, and Marx. Smith rejects most of Marx, approves most of Marshall and Keynes, and urges the application of orthodox economics to the problems of a socialist state. His argument is lucid and convincing, but not new. Dickinson pioneered this important thesis 30 years ago.

Since orthodox economics is applicable to socialist problems, "there is no need for any separate socialist system of economics . . ." (p. 15). But Smith is contemptuous of past efforts to apply orthodox economics to socialist problems. Such effort "suffers from the defect that it commences from what economists take to be the end of economic life—the maximization of output" or welfare (p. 95). Instead, socialist economists should plan how to eliminate economic conflict. By ending it they would "prevent the emergence of economic calculation as a necessity" (p. 135).

In Chapter 5 Smith argues that liberals can make capitalist states almost as equalitarian and productive as any socialist state, and cites English experience with income taxes and nationalization to support this point. He ignores or minimizes the enormous wastes due to capitalist competition, advertising, style cycles, product differentiation, inheritance, unemployment, etc.

In Chapters 6 and 7 Smith elaborates his principal, and highly original, thesis that socialism should be redefined as "the minimization of conflict arising out of economic relationships" (p. 9). By this he means that socialists should strive to create a society in which labor is so productive and brief that marginal effort causes no pain, in which capital is so abundant and incomes so high that marginal saving is painless, in which all goods are so plentiful they can be distributed free of charge (pp. 130-31). As he notes, "the Marxist definition of communism marches very closely with the [this] definition of socialism . . ." (p. 11).

The author admits that his thesis "certainly breaks away from the hackneyed text-book precept that 'human desires are unlimited'." He asserts that some persons of modest means are now satisfied with their lot, and pleads for "the universal acceptance of a modest standard of living" (p. 133). A socialist state should produce only those traditional necessities required for a modest but comfortable life. No new consumers' goods should be invented, no old ones improved. The socialist ideal is a static society because change creates economic conflict. In any case, "all the best things to eat and drink and all the more civilized ways of pleasing, adorning and amusing the mind and the body were discovered long ago" (p. 156).

Smith implies that, when anyone refrains from consuming a luxury, he reduces the real costs of other men. Hence, such behavior is an "ethical ideal." We reply that in a socialist state the costs of luxuries could and should fall on each consumer according to his consumption. Moreover, workers would continue to welcome painful marginal work which resulted in more than compensating pleasures of consumption. And such marginal work and consumption need cause no economic conflict. Competition for equally available, fairly priced goods and jobs is beneficial cooperation, not harmful conflict.

This book is largely a collection of miscellaneous rewritten articles and papers. As a result, most of the chapters are poorly related to each other and to the author's main thesis. Thus Chapter 8 is largely devoted to the balance-of-trade problems of a capitalist Britain. And Chapter 9 deals with recent Indian economic planning.

BURNHAM P. BECKWITH

Laguna Beach, California

Problemy politicheskoi ekonomii sotsializma: vypusk 1960g. (Problems of the Political Economy of Socialism.) By Y. A. KRONROD, editor. Moscow: State Publishing House of Political Literature, 1960. Pp. 304. 64 kopecks.

This work, written by members of the Economics Institute of the Academy of Sciences, is interesting as a contribution to what the Foreword describes as "creative scientific discussion." (The Foreword goes on to say: "The development of theory is manifestly impossible without creative debate about new problems. Accordingly the authors have by no means eschewed the posing of controversial questions; hoping that this will contribute to the development of an economic theory of socialism.") As a straw in the new wind blowing in Soviet economics, it may be noted that in argu-

ments with opponents there is a studied avoidance of name-calling. It is also to be noted incidentally that no representative of the rising school of Soviet mathematical economics is included. The volume represents a collection of articles grouped around the theme of the working of a socialist economy. Its dimensions are rather too slight for problems to be explored very exhaustively, and none of the contributors goes very deeply into his subject. Most of the contributions, however, are thoughtful and fresh, touch on important questions and are far from being repetitive exegesis.

A somewhat scholastic opening article by A. I. Pashkov, "On general and specific economic laws in Socialism," is followed by an interesting study (by R. G. Karagedov) of the place of profit as an incentive to the enterprise. The implication is that more emphasis should be laid upon it as the central economic instrument of *khozraschot*; although the writer remarks incidentally that "an important insufficiency of the existing index of profit is its extremely weak relation to the utilised productive funds [i.e. capital] of the enterprise." Kronrod, as a leading exponent of the value-principle in the price discussions of the past five years, restates his position on price policy in relation to the arguments of each school of opponents: the traditionalists (Maizenberg in particular), the advocates of an equiproportional mark-up (representing "surplus product") on *sebestoimost* (Kulikov, Sakov), and the price-of-productionists (Malyshev, Atlas, Vaag). With regard to the latter his reply is interesting, if not wholly convincing: namely, that the principle of price of production would only be relevant if there were "inter-branch [i.e., inter-industry] mobility and competition of capital"; since there is not, and investment is centrally planned and allocated, prices should be made to reflect the comparative labor expenditures of different products; and for the purpose of taking investment decisions the coefficient of effectiveness of investment can be adjusted as between industries to allow for differences in the size of basic and turnover funds (total capital) relatively to labor (pp. 127-28). This latter suggestion seems to be equivalent to using a special accounting price, of a price-of-production type, for purpose of investment decisions. It might well go some way to meet the problem that the price-of-productionists have in mind; but it could scarcely take account of differences in the amounts of capital used in producing the inputs of the industry in question, and to this extent would still leave comparative costs and hence the index of relative effectiveness distorted. Moreover, one feels inclined to ask whether *quasi*-mobility of capital may not be greater than the writer supposes, to the extent that under the current trend towards decentralization the initiative (at least) regarding investment plans is pushed down nearer to the enterprise.

Another noteworthy contribution is that of A. I. Notkin, known for his studies of "expanded reproduction" (i.e., dynamic problems with net investment). He is concerned with the "law of the optimum proportion between investment and consumption" (perhaps this will sound less strange to "western" readers if *zakon* is translated as "principle" instead of "law"). A principle emerges according to which the ceiling on investment is defined as such a rate of investment as will not create an upward pressure on retail

prices of consumer goods (p. 158), thereby causing, presumably, no fall in real wages—a condition admittedly unfulfilled in the prewar decade. But this definition is arbitrary: it does not explain what the initial price level is that must not be disturbed; and this, as we know, is determined *inter alia* by the rate of investment. Using an initial ratio of net investment to national income of 20 per cent and a capital-output ratio of 2.5 (called “the coefficient of investment needed to increase national income by one per cent”), the writer gives a series of examples to show that, with the share of investment growing by one per cent as national income grows, the level of consumption per head of population (assumed to grow by 3 million per annum, or about 1.5 per cent) will be higher after the seventh year than if the investment-share had remained constant or had declined by one per cent per annum. As regards changes in the capital-output ratio, he cites Soviet statistics which suggest that this has fallen since 1940, though unevenly in different industries, falling most markedly in building and rising in agriculture (where it is particularly high).

There follow two chapters of some 30 pages each, one on *kolkhoz*-property (by V. G. Venzher) and the other on the role of the credit system and ways of strengthening it (by V. M. Batyrev).

A concluding chapter surveys and dismisses the various western writers from Lerner, Dickinson and Beckwith to Mises and Hayek and Hoff who have discussed the economic theory of socialism. The writer (S. A. Khavina) is well-informed and well-read (including even Barone and Schumpeter's *History of Economic Analysis* in her ambit); but her treatment is disappointingly superficial and lacking in light and shade, and is not so very different from that of any other article of the past two or three decades on a similar theme. Although the writers surveyed are distinguished as “bourgeois” and “petit bourgeois,” their points of contrast are not explored, and the general tendency is to treat them as a “homogeneous reactionary mass”—as writers who uniformly try, in obscurantist fashion, to oppose an idealist-subjectivism notion of socialism to real socialism as actualized in Soviet economy.

The work is pleasantly produced, in an edition of 25,000 copies; it has no index.

MAURICE DOBB

Trinity College, Cambridge, England

Obshchestvenny uchet truda i tsena pri sotsializme. (The Social Accounting of Labor and Price under Socialism.) By I. S. MALYSHEV. Moscow: Sotsekgiz, 1960. Pp. 363.

Ocherki po voprosam balansa narodnogo khoziaistva. (Essays on Problems concerning the Balance of the National Economy). By V. A. SOBOLOV. Moscow: Gosstatizdat, 1960. Pp. 226.

These two books have this in common that they call for the same radical departure in price-setting and use the same arguments to justify their proposal. This is not surprising considering that Malyshev edited Sobolov's book. Since Sobolov's analysis of synthetic balances reduces to a rather pedestrian description of the work done in the Central Statistical Administra-

tion of the USSR on the subject (which does not warrant separate review), I shall comment only on the aspects of his work dealing with price theory, where he dovetails with Malyshev.

The main point Malyshev and Sobol' wish to put over is that the price of a good should be set to cover the average production costs (*sebestoimost'*) of all producers in an industry, plus a certain amount of profits, or "surplus value," proportional to the fixed and working capital used in this industry. The above rule, with certain exceptions, would apply to consumer goods as well as to producer goods. Their proposal diverges from present practice where prices are set at certain periodic intervals so as to cover variable costs plus amortization in producer goods industries (together with a very small profit margin proportional to costs), while most of the "surplus value" generated by industry is levied in the consumer goods' sector in the form of turnover taxes, representing the difference between retail prices (tending to equilibrate effective consumers' demand) and a lower level of production costs.

The strategy Malyshev and Sobol' have adopted to convince their readers is in itself instructive. They could not get away with an a-Marxist or, to use Oskar Lange's terminology, with a "praxiological" approach to the price-setting problem, based on efficiency considerations alone. L. V. Kantorovich in his controversial book on the optimal allocation of resources could afford to do this only because he is an established mathematician and not an economist in the Soviet sense of the word. Malyshev and Sobol', who are political economists, had to build a solid Marxist foundation for their ideas. This turned out to require a basic rethinking of economic categories and basic principles valid in the socialist stage of development. According to our authors, a socialist planned economy turns out "products" but not "market-commodities" (*tovary*). The "law of value," in the sense of a spontaneous, unplanned influence on allocation, does not operate under socialism, either in the producer-goods or in the consumer-goods sector, since free markets are practically nonexistent. Malyshev goes so far as to claim that prices on the kolkhoz market are "determined not by the law of value," e.g., by the spontaneous effects of supply and demand, "but by state prices in retail trade" (p. 70). He also denies the existence of a true market for consumer goods, since the government can always manipulate supply to equilibrate effective demand at any preordained level of retail prices (p. 132). The main point is that procurement and sales are planned just as systematically as production. The only law of value under socialism is the "constant and objective necessity of accounting for social labor and of observing the objective principles arising out of this necessity" (Malyshev, p. 49).

In the process of establishing these propositions, Malyshev and Sobol' go out of their way to assail powerful figures such as academician Ostrovitianov and to criticize the semiofficial handbook of political economy (*Politicheskaiia Ekonomia*). Several ideas in Stalin's *Economic Problems of Socialism in the U.S.S.R.* are scored (though there is no mention of Stalin by either author).

Do the nature of goods and the operation of the law of value under socialism warrant so much controversy? They do of course if one wishes to

convince Soviet readers that prices under socialism should be set consciously in much the same way as they would be formed under capitalism under the impact of market forces. For then it is essential to show how different the paths are that lead to the same result and that there is only a resemblance in form but none in content. Indeed, the matter is so delicate that Malyshev and Sobol' stress mainly the "differences in essence" leaving it to their critics to dwell on the convergence in form!

When Malyshev and Sobol' eventually turn to the business at hand—the correct principles that should guide price-setting practice—they begin by confounding certain views they consider erroneous. They have little respect for the "voluntarists" or "subjectivists," represented by L. Maizenberg and other price-setting officials, who have no clear theoretical principles and are pleased to tinker with the existing price system to stimulate or to inhibit the production or consumption of certain products. Malyshev objects, quite correctly in my view, that the voluntarists have no reliable standard by which to judge how they should influence allocation by price policy. Maizenberg, for example, proposes the manipulation of fuel prices to spur local coal production. This can easily be done, Malyshev agrees, but the main problem is whether or not this local production is advantageous from the viewpoint of the national economy as a whole. Here Malyshev seems to have stumbled across the familiar "dilemma of central planning," according to which economic calculation can only be used as a guide to efficient allocation decisions when the prices used in these calculations already reflect an efficient allocation.

With their other ("non-voluntarist") opponents in the Soviet price-setting debate, Malyshev and Sobol' share at least one view: they all agree that prices must be set equal to value including surplus product. What sets them apart is the question of how to divide up the total surplus product of the economy among individual industries. (This surplus product, or "accumulation," is defined, for practical purposes, as national income minus total wages and other incomes in the "productive sectors," the difference being equal to the total profits plus turnover taxes paid to the state or retained by these sectors.) Some economists would like to distribute this surplus among producers in proportion to production costs (*sebestoimost'*), and some, including academician Strumilin, in proportion to their wage expenditures; our authors, as I have already mentioned, would like to distribute the surplus *pro rata* with the fixed and working capital in each branch of industry. The idea in all three cases would be to set uniform prices for each industry's product equal to average costs in the industry plus the appropriate share of surplus product. This would serve as a norm of "socially necessary costs," against which the costs of individual producers, also including surplus product, might be compared. Malyshev shows, more systematically than Sobol', what nonsenses would arise out of pricing methods which would set profits proportional to *sebestoimost'* or to wages. Such prices would cause enterprises to concentrate on the production of material- or labor-intensive products; they would promote the consumption of (presumably scarce) capital-intensive materials, and so forth. To these methods Malyshev and Sobol' oppose their notion of "production prices" (*tseny proizvodstva*), equal to

average production costs in the industry plus a percentage of the industry's fixed and working capital equal to the ratio of the yearly surplus product generated by the productive sectors to the value of the fixed and working capital of these sectors. They seek to prove that this pricing method would give the right answer to problems of investment efficiency, would cause the right materials to be substituted, and, finally would create an incentive for enterprises to economize on their fixed funds and to accelerate their turnover of working capital. (It has been argued by some authors in the West that, for the purpose of regulating the work of socialized enterprises, interest on fixed capital need not be included in the prices of producer goods in Soviet-type economies, inasmuch as enterprises have no control over the capital entrusted to them. But, as Malyshev points out, enterprises often have a choice between ordering more or less capital-intensive goods; they are likely to hoard surplus equipment if they have no incentive to report it to superior authorities; finally, they may be induced to request less expensive equipment to save on amortization and interest costs.) In his discussion of prices and investment alternatives, Malyshev shows a higher degree of sophistication than most Soviet economists: he is aware of the significance of resource limitations (e.g., of the scarcity of capital) and he shows familiarity with the notion of opportunity cost (p. 200; see also Sobol', p. 71).

So far I have not commented on the intrinsic value of the pricing method proposed by the two authors. Would prices set in this manner qualify as efficiency or opportunity-cost prices? I think they might come closer to satisfying this requirement than either present prices or any of the alternative schemes considered; nevertheless, they also suffer from a number of defects: (1) The unique profit rate on capital is largely arbitrary. In effect it is assumed that capital is the only scarce factor besides labor and that it generates all profits. This ignores returns to other factors such as land and mineral resources which may also be a source of profits or taxes in the Soviet Union (e.g., turnover taxes on gas and petroleum). Wherever there are diminishing returns, there must be returns to scarce factors. (2) In a Soviet-type economy, where almost all the saving is done on government account, the ratio of profits and taxes to the capital stock will tend to vary with the level of investments; but the true marginal efficiency of capital need not move in parallel fashion. (3) It is only by coincidence that the prices of consumer goods arrived at by this method would clear the market at prevailing income levels. It would be optimistic to expect that relative market supplies could be adjusted to consumers' demand at these prices without running into bottlenecks and rising marginal costs. (4) Once prices were set at the level of Malyshev's "prices of production," a completely new price structure would emerge. The capital stock would have to be revalued. Neither the ratio of surplus value to national income nor the ratio of "accumulation" to the capital stock would be exactly the same as before. Prices fully conforming to the new formula could only be arrived at by successive approximations.

Malyshev and Sobol', unlike Kantorovich (to whom they unfortunately never refer), are inhibited by their strict adherence to Marxist tenets. They recognize the scarcity of capital and they would like to express this scarcity

in the price system, but they must maintain the fiction that labor is the source of all value. By dint of numerous references to the third volume of *Capital*, they try and demonstrate that the surplus value generated by labor under socialism should be redistributed according to the amount of capital attached to each worker. Although this is only a step toward a theory of efficient prices, it is still too far afield for most Soviet political economists, who have expressed their negative attitude on these new proposals in a number of adverse reviews. There are, however, some exceptions. As one of the critics regretfully put it, "the idea of a socialist price of production . . . has received particularly strong support from engineering-technical personnel, who are attracted by the fact that it . . . purports to offer . . . an automatic answer to all complicated economic questions." (A. Probst in *Voprosy Ekonomiki*, no. 3, 1961, p. 81.) He might also have deplored that a number of economists interested in mathematical methods, including academician Nemchinov and V. D. Belkin, profess views similar to Malyshev's. It is interesting, as a matter of fact, that the lineup of Soviet economists for and against Malyshev and Sobol' is much the same as it was for and against Kantorovich's book when it appeared in 1959. For example, A. Katz who distinguished himself by his vigorous attack on Kantorovich in 1960 assailed the "price of production" theory and the notion of a unique profit rate on capital in 1961 (*Voprosy Ekonomiki*, no. 4, 1961). What disturbs these critics of course is that both the Kantorovich and the Malyshev-Sobol' approach are irreconcilable with their interpretation of the labor theory of value. Ia. Kronrod articulated their common point of view as follows: "If identical . . . masses of average labor, expended on different branches, more or less intensively equipped with capital, were to represent different quantities of socially necessary labor, then this means that these identical masses of labor would perform as creators of different quantities of value; in other words value would be determined not by live labor, in the form of abstract labor, but by some sort of a combination of labor and means of production." He concluded that such ideas conflict with the labor theory of value and that they "basically coincide with the theory of the productivity of factors of production." (*Voprosy Ekonomiki*, no. 10, 1960, pp. 90-91.) If Kronrod's interpretation of Marx is correct, so much the worse for Marx and for Soviet price theory.

JOHN MICHAEL MONTIAS

Yale University

Money, Credit and Banking; Monetary Policy; Consumer Finance; Mortgage Credit

The Secondary Mortgage Market—Its Purpose, Performance, and Potential.

By OLIVER JONES AND LEO GREBLER. Los Angeles: Graduate School of Business Administration, University of California, 1961. Pp. xv, 281. \$6.50.

This book is of interest and value in the fields of marketing, finance, real estate and other fields of applied economics. It is a type of investigation which has been largely neglected although it should be a kind of study which is one of the economist's greatest contributions.

What legal setting will make a free-enterprise market feasible and efficient in a particular field? In this study the authors have considered the impediments to a market in which mortgages can be readily shifted from one holder to another. With minor exceptions such a market is notably lacking at the present time. The authors are at pains to point out that the Federal National Mortgage Association has never been permitted to operate as a true secondary market where there is continuous free buying and selling, and that it does not promote a true market. It has too often operated as a one-way street, buying but not ordinarily selling. The FNMA operations consist primarily of purchasing mortgages at the time of origination and holding them indefinitely.

This study finds that the same reforms which would promote a secondary mortgage market would also greatly improve the primary market. The nature of the study can best be conveyed by simply listing some of the major conclusions and recommendations of the authors. The interest rate charged on FHA and VA mortgages should be market determined. Competition among mortgage lenders should be promoted by standardizing statutory restrictions on terms that may be offered on conventional mortgages. Competition among mortgage lenders should also be promoted by removing restrictions on the geographic area of their lending operations. A uniform mortgage code should be adopted by all states. Statutes and regulations that particularly circumscribe mortgage lending by commercial banks should be reviewed with the objective of removing anachronistic restrictions on the flow of mortgage funds. A thorough study should be directed to the feasibility of encouraging competition between mortgages and other investments by more nearly equalizing the ability of mortgage lenders to attract savings and invest in nonmortgage assets.

Market makers and mortgage companies should be allowed to obtain federal charters, which, in turn, would place them under federal supervision. Statutes that require portfolio lenders to make on-the-site inspections should be revised. A classification system for conventional mortgages should be developed. The legal and administrative procedures that surround the transfer of a mortgage should be simplified.

The authors do not have confidence that these reforms would automatically generate a strong, thriving and adequate secondary mortgage market. They recommend the creation of a Federal Central Mortgage Corporation which could buy and sell mortgages and make short-term loans to market makers and portfolio lenders. The FCMC would also charter and supervise market makers and mortgage companies, conduct the studies and analyses necessary to develop a system for classifying conventional as well as federally underwritten mortgages, and take appropriate actions to encourage state governments to cooperate with the program of reform. The corporation would, further, collect and disseminate the market information needed by market makers, such as current data on prices and activity, provide the centralizing focus necessary for bringing the net balance of supply and demand conditions to bear on mortgage prices, and issue debentures tailored to the needs of untapped sources of savings.

Jones and Grebler have done an outstanding work in evaluating rules of law and role of government which will be conducive to private enterprise ac-

completing needed economic goals in an efficient manner, not only in the field of secondary mortgage markets, but in considerable measure with respect to the real estate market, the mortgage market and the financial markets in general.

HOMER JONES

Federal Reserve Bank of St. Louis

Bank Holding Companies. By GERALD C. FISCHER. New York: Columbia University Press, 1961. Pp. xii, 215. \$5.50.

One of the principal structural problems and perhaps the most bitterly contested issue in commercial banking today is that of independent unit versus multiple-unit organization. Dr. Fischer has made a significant contribution to the factual background and analysis of this question in his recent book on *Bank Holding Companies*. Such a publication is long overdue, since no general work in this area has appeared since Professor G. T. Cartinhour's *Branch, Group and Chain Banking* (1931). The book is logically organized, and is presented in precise, effective style. By means of questionnaires and personal interviews with holding company officers and competitive independent banks, the author has collected information which throws new light on the issues.

The first three chapters provide a historical summary of chain and group banking from its origin in the 1880's through 1929. Reasons for the rapid expansion during 1927-1929 are developed, along with federal and state regulatory actions. The next three chapters carry on the survey from 1930 to 1961, dealing with growth, comparative suspension records, and the course of federal control. A summary of the Bank Holding Company Act of 1956, together with its administration by the Board of Governors of the Federal Reserve System is also included.

Chapters 7 through 9 deal with the competitive position of holding company banks. The author finds that, while constituent banks benefit from a number of holding company services, there is no very basic difference between them and competitive independent banks which often enjoy comparable services from city correspondents. The most fully utilized service by the group organization is in the investment area where the company's specialized staff is able to give small member banks much needed assistance. Other helpful services pertain to loans, reserve position, operating methods, tax questions, and legal counsel. The author also finds that directors of group banks are "composed almost completely of individuals from the community who are independent of the holding company."

Expansion in number of units has occurred principally by merging existing institutions rather than by formation of new banks. In fact, 138 banks were acquired by the 15 main groups between 1948 and 1960. While other factors were operative, shareholders of independent banks decided to merge in most cases because they were offered a more valuable and more marketable security in exchange for their shares. Moderate though not striking benefits, the author concludes, usually accrue to both small banks and their communities from group affiliation. While interest rates paid on deposits and charged on

loans are determined as a rule at the local level, communities benefit from better services as a consequence of keener competition. This is evidenced in particular by more aggressive loan policies, fuller use of cash resources, and modernization of equipment and facilities.

In conclusion, Fischer believes that "a group's greatest contribution stems from its capacity to provide many of the facilities of a large bank without extensively sacrificing local autonomy. . . ." He visualizes further intrastate development of group banking as "the only satisfactory, even though temporary, answer" to problems which the unit banker cannot solve, and which in the end make widespread branch banking inevitable.

International Economics

International Trade: Theory and Economic Policy. By JAROSLAV VANEK. Homewood, Ill.: Richard D. Irwin, 1962. Pp. x, 426. \$7.50.

To the numerous texts dealing with international economics is added this high-powered survey. Depending upon the equipment available to the student, this book carries or pushes him to the furthestmost boundaries of the subject. It is certainly not an elementary and hardly an intermediate text. The approach is persistently advanced employing many of the most recently developed tools of analysis.

Historical and institutional analysis are almost completely absent—mention is made of *an* "international monetary fund" but never to *the* I.M.F. The use of algebraic methods is limited, but mathematical and particularly geometrical methods are extensively employed. The author's aim is to bring together the most contemporary and original contributions on the various frontiers of international economics, to consolidate them, and present a simplified analysis based on these developments.

Conforming to the widely accepted practice of quadripartite arrangement for texts in international economics, this book deals firstly with the balance of payments and national income accounts; secondly with the balance of payments adjustment mechanisms; then with the pure theory of international trade, and finally with the problems of economic policy for the international economy. Conformity however ends with this concession, since the contents are both original and synthetical with a wide-sweeping scope. The author skillfully covers the major ideas of complex international economic theory and presents the components in new lights.

Throughout the study there is an attempt to recognize the economist's obligation to provide answers to the important policy questions. Of greatest relevance here is the attention given from time to time to policy problems of economic integration. Vanek attempts to apologize for the extreme oversimplifications of reality presented but he points out that mismanagement frequently results from a neglect of the pure theory of international trade which provides an understanding of the setting and conditions of monetary balance of payments equilibrium, the focus of most attention today.

The balance of payments accounts are treated from both the flow and stock points of view and linked with national and sectoral accounts. The approach is elaborate, yet Vanek formalizes the traditional approaches making for a tighter system of analysis. It exposes some of the weaknesses in the façade of international economics as for example the difficulties of dealing with the foreign goods component in domestic consumption and government expenditure. Once presented, however, the accounting system developed is abandoned appearing irrelevant for the rest of the book.

In Vanek's view the absorption approach to balance of payments adjustments adds little to the income analysis derived from the more conventional income approach. Nevertheless he finds no solution to the immeasurable difficulties created by considering price and income changes simultaneously involved in the adjustment process. Since he considers that capital transfers and donations, unlike current transactions, are not very responsive to the rate of foreign exchange, he is able to elaborate on their separate influences on the foreign exchange market, export and import prices and hence the terms of trade, concluding that the change in the exchange rate will have the same sign as the autonomous transfer under stable conditions.

The treatment of the pure theory of international trade is comprehensive and represents a masterly compression of diverse theory. Vanek makes considerable use of Meade's geometry in establishing the conditions for general equilibrium in international trade after treating numerous supply and demand conditions and attempting to justify the use of community indifference curves. The application of welfare theory to foreign trade conditions supplies Vanek with the rather conventional conclusion that free international trade can always generate greater satisfaction to the communities involved than can domestic trade by itself.

Policy matters given most attention include commercial policy or direct trade policy, general economic policy for internal and external balance, and policy for a customs union. Again considerable use is made of involved geometry. Details of a general model employing the Tinbergen theory of economic policy are presented, although the mathematical relationships are not developed. Vanek finds that use of the exchange rate as a tool of policy should be avoided in coping with short-run disequilibria. Monetary policy tends to affect both the current and capital accounts of the balance of payments in the same direction, whereas fiscal policy affects them differently. He finds that the three policies have to be used in some appropriate mix in order to achieve the three target objectives of full employment, price stability and external balance. He does not incorporate directly into the model the objective of economic growth.

One of the most interesting chapters both from the point of view of economic theory and contemporary public policy is the last, which deals with the theory of customs unions. Vanek makes use of the concept of the excess offer curve which is based on joint offer and demand in two commodities to and from a third country, and he establishes general equilibrium solutions for all three countries with the aid of Meade's geometry. From the point of view of equity and economic efficiency most of the analysis points to the great de-

sirability of complete free trade by the union. It is obvious that new internal and external balances will have to be established by each country; Vanek however does not extend this part of the analysis very far.

Some of the areas dealt with rather lightly in the book are the problems of international liquidity, foreign aid, and economic development. Attention given to international trade and economic growth is very brief especially in view of the wealth of new literature on this aspect and the relevance of the topic in current economic policy.

Some will question the value of using throughout such high levels of abstraction, which provide only limited policy conclusions. Others will ask whether such complicated analyses were really suitable for a text and whether the complex theory can serve as any guide to empirical studies. Although the arrangement and the exposition of the book are logical and beautifully pedagogical, the author is not always easy on his reader. For example, assumptions are sometimes established, then relaxed or dismissed, and then re-established within one short passage; each conclusion reached must be carefully related to the special framework within which it was established. The reader is continually challenged to work out alternative methods of analysis or to extend into even more complex areas the examinations under study.

The book contains a useful selected bibliography and a short appendix describing the basic tools of analysis and setting out the limits of the mathematical application. The profoundness of the study makes it essential reading for the graduate student. Any student will need to bring much theoretical equipment with him in studying this book; however it is certain he will take much more away.

Canadian-American Dependence: An Interindustry Analysis of Production and Prices. By R. J. WONNACOTT. Contributions to Economic Analysis, No. XXIV. Amsterdam: North-Holland Publishing Co., 1961. Pp. xiv, 143. \$4.50.

The Canadian Dollar, 1948-1958. By PAUL WONNACOTT. Canadian Studies in Economics, No. 13. Toronto: University of Toronto Press, 1960. Pp. xiii, 162.

Within a few months of each other, the Wonnacott family has produced two solid contributions to our knowledge of the Canadian economy. R. J. Wonnacott applies the technique of interindustry analysis to the measurement of interrelations between United States and Canadian prices and production. His contribution goes beyond these measurements to some pioneering methodological work on interregional models and on input-output solutions subject to constraints on industrial capacity. Paul Wonnacott's study is the most substantial effort yet to evaluate the results of Canada's flexible (since 1950) exchange rate. Because the debate over fixed *versus* flexible exchange rates has reached the point where laboratory experiments are sorely needed, this appraisal has great potential significance.

There are several possible approaches to international input-output analysis: each region has the same technical coefficients; each region has different technical coefficients for producing the same products; each region produces a different set of products. The first approach requires some further assumption, such as the existence of nontraded goods, to make it differ significantly from a unified national model. The second and third turn out similarly in the usual interindustry model, which allows only for relations of complementarity among inputs. Be they similar or different, each region's products are traded and transformed only on the basis of fixed proportions. R. J. Wonnacott has a reason for making the distinction, however, between the cases of differing regional coefficients and differing regional products. He is interested in interindustry models with some sectors subject to constraints of maximum capacity. When a U.S. industry is pushed to capacity operation in satisfying an assumed bill of final demand, such a model allows the competing Canadian import to make up the deficiency.

Workers in input-output analysis have found capacity limitations easy to handle when they can make do with an iterative rather than a general solution to the model. Wonnacott shows, however, that a unique general solution not only exists in the case where capacity limitations are present but that it is computationally feasible if they are few enough. This he demonstrates in a model having a capacity limitation on the American nonferrous metals industry (apparently picked at random for this honor). As often happens, the empirical results of this interindustry analysis contain few surprises. The Canadian and American sectors most dependent on the other country's production are the heavy exporters or those dependent on export industries. Canadian export volumes, however, turn out to give poor guidance to the relative dependence of various Canadian producing sectors. Comparing equal proportional changes in the economic activity of Canada and the United States, the smaller size of the Canadian economy condemns it to showing its well-known greater sensitivity. Were it not for the size difference, however, the shoe would be on the other foot: comparing equal absolute changes, the United States shows significantly greater sensitivity to Canadian activity.

A second section of R. J. Wonnacott's study explores a different feature of economic dependence—the sensitivity of the Canadian price level to external price increases. Interindustry models are less often called to answer this question and respond only subject to special assumptions. The Canadian economy might avert domestic effects of an external inflation by an adjustment of its flexible exchange rate. Without this adjustment, cost escalation and inflationary pressure on the prices of "international" goods will transmit some portion of the foreign inflation to the domestic cost of living. If the only influence on Canadian prices is through increases in the prices of international goods, a 10 per cent inflation abroad raises Canadian prices by 3.9 per cent; but if Canadian wages undergo a cost-of-living adjustment, the figure rises to 5.5 per cent.

"On the whole," concludes Paul Wonnacott, "the Canadian experience

with a flexible exchange rate has been a happy one." The Exchange Fund Account has operated properly by leaning against prevailing exchange-rate movements in most months. (It could, however, improve its performance by leaning more heavily as a cumulative change proceeds, rather than easing off as it has typically done.) Private short-term capital movements on balance have stabilized the balance of payments, both by moving counter to the sum of the current and long-term capital accounts and by tending to nudge the exchange rate toward its trend value. The exchange rate fluctuated over a range of 13 per cent in the years 1950-57 without visibly disrupting the flow of trade or long-term capital.

Flexible exchange rates, however, have not contributed much to the successful application of tools of domestic policy. The flexible rate created a great potential freedom for Canadian monetary policy, but this monetary freedom was not used to create monetary conditions significantly different from those in the United States. Exchange-rate movements in the 1950's might have aided the control of inflation in Canada by tending to worsen the current-account balance when inflationary pressures were strongest; in fact, they performed indifferently by this test. Paul Wonnacott is not dismayed by the mediocre performance of the fluctuating exchange rate in assisting domestic policies: the need for such assistance is clearly less than in times past.

The favorable verdict on Canada's fluctuating exchange rate does not portend equal success for the device in other countries. The study documents the continued functioning in the 1950's of the special mechanisms which tend to keep Canadian international payments and receipts in equilibrium. An increase in imports of investment goods still follows directly upon an inflow of long-term capital. There is strong support in the past decade's quarterly data for the relative-cycle hypothesis, which asserts that an increase in the growth rate of Canadian GNP relative to United States GNP tends to raise the flow of long-term capital to Canada. Since this increase also tends to deteriorate Canada's current account, the net result again equilibrates the Canadian balance of payments without any help from the exchange rate. Finally, there are such classic institutional features as the popular belief in parity between the American and Canadian dollars and the good gray conservatism of Canadian monetary policy to discourage destabilizing speculation.

Paul Wonnacott's study is an able and scholarly investigation of a complex pattern of policies, combining insight, good judgment, and a respect for the weaknesses of the available statistics. Many economists would have used formal statistical inference in dealing with these questions, however, rather than contenting themselves with a verbal analysis of charts and tables. Furthermore, the book presents a cluttered appearance from the author's effort to cover many topics in few pages and his inability to resist the temptation to detour into commentary on previously published research.

International Payments Imbalances and Need for Strengthening International Financial Arrangements. Hearings before the Subcommittee on International Exchange and Payments of the Joint Economic Committee, May 16, June 19-21, 1961. Washington: Superintendent of Documents, 1961. Pp. iii, 340. \$1.00.

Report of the Subcommittee on International Exchange and Payments of the Joint Economic Committee. Washington: Superintendent of Documents, 1961. Pp. 26.

These two publications of the Joint Economic Committee provide a relatively concise introduction to the nature and magnitude of the liquidity problem and the various proposals which have been advanced to cope with it. While they should prove useful to the nonspecialist who is interested in learning what the fuss is all about, students of international finance are not likely to find anything novel in them. For the most part, the papers presented by members of the academic community are a rehash of views already expressed on numerous occasions with little attempt either to answer criticism or to acknowledge, for comparative purposes, the existence of alternative proposals. The papers presented by government officials, on the other hand, are little more than rationalizations of actions taken (or not taken) to meet past crises.

The chief criticism that can be levelled against the papers and the Report is the general failure to examine the broader issues raised by the recurrent U.S. balance-of-payments deficits and the liquidity crisis. Professor Harry Johnson was one of the few contributors who even suggested the possibility of a flexible exchange rate system as a solution to these problems and he quickly backed away from a discussion of this solution with the remark that "it would amount to replacing the present international monetary system [and hence] that it lies outside the scope of the Subcommittee's inquiry" (*Hearings*, p. 173). One wonders whether this was a self-imposed constraint or one imposed by the subcommittee. Likewise, despite the overwhelming importance of the relationship between domestic fiscal and monetary policies and the outcome on the balance of payments, little systematic attention was devoted to it. In lieu of serious discussion of these and related problems, most contributors contented themselves with general statements concerning the need for international cooperation, of the necessity to limit the flows of hot capital, and of the desirability of increasing, by one means or another, the volume of international reserves.

The mediocre level of the papers read by the members of the academic community on what is generally regarded as one of the most important current economic issues raises a question as to whether the economics profession is taking one of its more important tasks seriously enough. This task is simply one of educating legislators on economic matters. The presentation of papers before Congressional committees is one of the chief ways by which this objective can be achieved. The failure to take advantage of the opportunity to deliver a paper before a Congressional committee constitutes a disservice both to the economics profession and to Congress.

**Business Organization; Managerial Economics;
Marketing; Accounting**

The Firm: Micro-Economic Planning and Action. By NEIL W. CHAMBERLAIN. New York: McGraw-Hill, 1962. Pp. ix, 428. \$7.95.

The past year brought forth two significant books in which economists and a management scientist concern themselves intensely with accounting problems.¹ Chamberlain's new work may be interpreted as a manifestation that this converging trend towards the area of accountancy continues at present. The interest which a well-known economist shows here in the problem of *budgeting*, reflects the prominence to which this comparatively young branch of accounting has risen; it gives an inkling of the great expectations with which this discipline is generally regarded. It also is interesting to see this subject being treated from an unconventional viewpoint and being integrated into microeconomics. But we regret that the treatment relies exclusively on the descriptive, institutional approach and pays no attention to the analytical and mathematical tools for which planning and budgeting constitute a potential area of application. Such a methodological argument, however, lies almost beyond the range of criticism justifiable in a review; especially since Chamberlain's interest in budgeting arises not out of a theoretical consideration, or an evaluation of the future, but out of an "examination of the business unit at first hand, to see for one's self how it operates, to discuss with its managers why they do what they do, and try to hypothesize from what is found." The book thus represents an honest attempt at finding a more realistic approach to the theory of the firm than the one presently predominating. Whether such an empirical investigation (which relies partly on interviews with executives, partly on a questionnaire received from about 250 corporate officials, but primarily on accounting and management literature²) offers sufficient breadth and depth in a course of business economics is open to doubt. In most cases the material presented in the book will have to be supplemented by the conventional analytical tools of microeconomics. Since the book is not merely a text, but has reference character as well, its market will extend to general academic circles and the business world. It is written in a broad but pleasant and very readable style and contains a wealth of valuable information as well as stimulating ideas. One flaw is caused by the lack of expertness wherever subtle accounting competence is called for. This shortcoming leads, apart from terminological discrepancies, to an occasional superficiality and in one case to a definitely misleading sec-

¹ C. W. Churchman, *Prediction and Optimal Decision*, Englewood Cliffs 1961, esp. Ch. 3 and 13, and E. O. Edwards and P. W. Bell, *The Theory and Measurement of Business Income*, Berkeley 1961.

² It is interesting to note the literature on which Chamberlain's book is based: over half of the citations (in total more than 250) are based on accounting and budgeting literature (of which two thirds refer to publications of the National Association of Accountants, formerly N.A.C.A.) only about 10 per cent are based on literature of economics (including hearings before sub-committees and the author's previous work). The remaining quotations refer to general management literature (in which reports of the America Marketing Association, the *Controller*, etc., are repeatedly encountered).

tion: the presentation of the "flow of funds statement" in Chapter 2, reveals that the essence of the flow of funds approach as developed in business accounting has not been comprehended and Exhibit 4 which purports to depict this statement does not actually do so. The fundamental idea of specifying in the flow of funds statement the changes of *only long-term* (balance sheet) items—in order to show the sources and uses of the *global* balance of all short-term items (the changes of which *must* be articulated in a *separate* working capital schedule)—seems to this reviewer to have been completely missed.

The first five chapters prepare the setting by discussing the aspects of planning in relation to economics, various accounting statements and tools, the distinction between short-term and long-term planning and the reaction of actual practice to these plans, and, above all, the objectives of the firm and the planning process together with the alternative possibilities of measurement. Most of these and subsequent chapters are endowed with examples from actual practice (frequently even the names of the pertinent companies are quoted). This offers a rich and kaleidoscopic picture that supplies an insight into the planning activities of actual business in a concentrated form, hardly to be encountered elsewhere.

Chapters 6 to 10 (starting with the budgeting philosophy) deal with the various sub-budgets from the sales forecast to the production and expense budgets under incorporation of the pricing problem. What the author offers is not a mere listing or description of these budgets; he illuminates all these planning phases in a sparkling light that brings hundreds of aspects and details to the fore.

Chapters 11 to 15 are concerned with the coordination and reflection of the sub-budgets and their data in the projected operating statement, the capital budget, the projected balance sheet, the projected "flow of funds" (cash budget!) and the corporate plan as a whole. Thus the controllership function, the interdependence of the variables (if this expression may be used in connection with an institutional work) and the approximation-methodology form the undercurrent of these chapters which are no less richly endowed with illustrations from business life than the preceding parts of the book.

The remaining five chapters are organized around the problem of variances from standards and also contain the concluding summary. This part would have offered an opportunity for outlining systematically the distinction and relation between budgeting and standard costing, a problem that has not been perceived or at least not been articulated; the term standard costing or standard cost accounting does not even appear in the subject-matter index.

The trend towards accounting problems and the author's expressive conviction that instead of focusing exclusively on price decisions: "much is to be gained by reorienting micro analysis to the same interest in income flows, which characterizes national income (macro) analysis," and the book's closing sentence: "it seems likely that the budget (expressive of anticipations and intentions) may become as useful an analytical concept to economists in understanding the firm as it has proved a functional device to management in administering it" epitomizes the philosophy of the work under re-

view and gives reason for hope that economists begin to integrate accountancy into the mother-discipline. Thus the book will find acclaim among all those who wish to obtain an insight into the planning process of the firm as it is carried out in actual practice, who long for a description of the "is" instead of the "ought to be," who know to appreciate a sample out of economic life, even if it is difficult to determine how representative the sample is.

RICHARD V. MATTESSICH

University of California, Berkeley

Changes in the Location of Manufacturing in the United States Since 1929.

By VICTOR R. FUCHS. New Haven and London: Yale University Press, 1962. Pp. xxi, 566. \$10.00.

This is the first of a series of studies sponsored by the Committee on Analysis of Economic Census Data. This useful series is planned to contain further volumes on the industrial structure of large diversified firms, price-cost behavior in manufacturing, concentration in manufacturing, and the structure of retail and wholesale trade. Perhaps it will be possible, on future occasions, to reduce the time interval between a Census and the date of publication of such analyses.

The author of the present study has made two comparisons of Census data: 1929 with 1954, and 1947 with 1954. These comparisons fall under five headings: (a) extent and geographical direction of changes of manufacturing activity as a whole (Ch. 3, 4); (b) changes in the geographical distribution of industrial patterns (Ch. 5, 9); (c) relative changes in location of market-oriented industries and of labor-oriented industries (Ch. 6); (d) changes within the separate geographic divisions (Ch. 7); (e) changes by major industry groups and by industry (Ch. 8).

We must confine the following summary and discussion to the first three of these headings.

a. After surveying the changes that have taken place, the author presents measures of the area differentials in the rates of growth of manufacturing and segregates the part of these differentials which may be ascribed to differences between the areas in industrial structure. These adjusted differentials are found to be negatively correlated with the relative extent of unionization in the areas (but not with wage levels), with a climatic index, and with availability of building space, as measured by population density. The differentials are also correlated with shifts in population and income, but here causal relations run both ways and can only be examined on a less aggregated basis (see below under c). But we do want to note here the author's finding that net migration into the areas was strongly correlated with the relative wage levels (adjusted for industrial structure), for this runs counter to the slight importance some labor economists have attributed to wage differentials in explaining migration.

b. Under this heading we discuss what the author calls "industrial mobility." The term is unfortunate since, as he points out himself, an industry's geographical distribution changes far more often through differences in the industrial distribution of growth of industries than through physical move-

ment of plants or firms. The changes under this rubric are measured as the total of percentage gains in value added or employment of an industry for all states in which the relative shares of that industry increased (this must, of course, equal the sum of the percentage losses for all the states for which the relative share decreased). The author notes that these measures will necessarily increase with increasing relative fineness of industry classification. He is careful to take this and the possibility of spuriously high "mobility" measures for industries with low specialization ratios (due to Census practices of classifying multiproduct plants) into account in his analyses.

The "mobility" measures are negatively correlated with average hourly earnings in the different industries, possibly reflecting the pull of the large reserves of low wage labor in the South on industries using much unskilled labor. Creamer's finding for an earlier period that both the geographically highly concentrated industries and ubiquitous industries did not show much change in geographic distribution is confirmed by the author for subsequent periods.

"Mobility" is positively correlated with growth rates and the usual measure of concentration of ownership for the different industries. This latter relation has not been anticipated in the literature; rather the opposite has been asserted, namely, that monopolistic conditions, by not exercising such consistent pressures for economic location, may lead to less "mobility" than competitive conditions. It is not clear, however, that in general, when an industry grows, the most economical geographical pattern of new capacity is necessarily so different from that of the old capacity. (For some industries this is undoubtedly true, but the present discussion relates to "mobility" for manufacturing as a whole.) Moreover, a classification of industries by concentration of ownership is not coterminous with one according to degree of monopoly, for industries with widespread ownership often have highly localized markets in each of which there is a large degree of monopoly.

c. Market-oriented industries are here taken to be industries which are oriented to local (or sectional) consumer markets as well as their local suppliers. For such industries only can changes in geographic distribution be ascribed to changes in the extent, incomes or tastes of the local population. In 1954 these industries—the classification is still necessarily somewhat subjective—accounted for some 11 per cent of total employment in manufacturing. Some indication that the direction of causality runs from manufacturing activity to growth of income and population rather than in the reverse direction is offered by the finding that the correlations between per cent of comparative growth of industries on the one hand and of population and income on the other are practically the same for market-oriented industries as for others.

It is found that for labor-intensive industries the area differentials in growth of manufacturing had a much stronger (negative) correlation with the relative extent of unionization in the different areas than for other industries.

Half of the 300 pages of text consist of tables and these are backed up by some 240 pages of detailed appendix tables. In order to compile these the

author had access to data not found in the published Censuses. The volume will long remain indispensable to a varied array of research workers.

HENDRIK S. KONIJN

Yale University and The University of Sydney

Local Subsidies for Industry. By JOHN E. MOES. Chapel Hill: The University of North Carolina Press, 1962. Pp. viii, 252. \$6.00.

Professor Moes undertook, in the opinion of this reviewer, a difficult task when he decided to write his book. He ventured into a relatively unexplored area of economics which deals with subsidizing industry by organized efforts of small communities. His difficulties were magnified by the following two considerations; in the first place he expresses views and opinions, as he himself states, that have been condemned by almost all economists, tax experts, lawyers, and municipal officers. In the second place, he deals with facts and arrangements that in most cases have been extremely informal, confidential, sometimes secret, very frequently not authorized by law, and occasionally definitely illegal. Whether or not one agrees with Moes' views and analysis, one has to admit that he has presented his case in a convincing and lucid fashion and has made an interesting contribution to the rapidly growing science of regional economics.

The main thesis of Moes is that a community, when faced with local unemployment, should offer a subsidy in order to attract an industry to its area, and in this way to eliminate part or all of its unemployment. The community should, in Moes words, invest in buying an industrial payroll. Such a local subsidy would increase the community's income, would absorb its unemployed or underemployed men, and by doing so it would be beneficial and profitable not only to the community concerned but also to the economy as a whole.

Moes' presentation consists essentially of two parts; a theoretical analysis presented in Chapters 1, 6, 7, and 8, and an empirical and institutional review presented in Chapters 2, 3, 4, and 5 of his book.

In the analytical part of his study he states that local unemployment is due to the rigidities of wages. In many communities there are people who are unemployed because their marginal revenue product is below the prevailing wage rate. As wages cannot be locally lowered by an individual industrial entrepreneur who is in the process of deciding on a new location for his plant, a wedge between the entrepreneur's labor cost and the actual wages paid to the workers has to be driven. Subsidies provide this wedge. No matter what form subsidies will take (loans, grants of land or of buildings, tax exemption, lower tax assessment, provision of free utilities) essentially they always subsidize payroll. Subsidies should be granted in all cases where there is local unemployment, and should continue until the marginal cost of subsidies is equal to the marginal revenue in form of increased income of the community.

Quite rightly Moes points out (Ch. 7) that the benefits from a subsidy that accrue to a community are not limited to the amount of the actual pay-

roll that a newly established industry disburses to its workers. The spending of this payroll by the workers will produce a multiplied effect upon the community's income, and this total effect should be considered in evaluating the benefits resulting from a subsidy. After devoting a whole chapter to the analysis of this local multiplier, and after presenting a rather convincing case for this type of analysis, Moes rather unexpectedly and surprisingly concludes his chapter by saying that "The multiplier approach is not very suitable to carry this analysis further. . . ."

In the last chapter of his book Moes combines his abstract analytical approach from the preceding three chapters with some realistic empirical observations. He believes that "gains from subsidizing industry rest on the inefficiency of resources allocation which unemployment implies" (p. 172). The process of competitive subsidizing by various communities would eliminate the existing imperfections of the markets and would lead to a more optimum allocation of resources, especially of labor, and by doing so, it would bring the whole economy closer to the optimum postulated by a perfectly competitive model. In his opinion subsidies would not, and should not, lead to the reallocation of existing plants; they should only influence the location of new plants. Thus "competitive subsidies in the absence of growth would contribute very little to the economy at large" (p. 179).

Most of his cases described in the empirical chapters refer to the South and deal with the efforts to eliminate disguised unemployment which so frequently prevails in agriculture in that part of the country. He describes the attempts of various private and public agencies to attract industry to a particular locality by offering a variety of financial inducements to entrepreneurs who are contemplating a new location for their plants. In the final analysis Moes reaches the following conclusions: (1) any community faced with unemployment could and should solve the problem of unemployment by attracting new industry, (2) in most cases a very small amount of subsidy would produce a very substantial increase in the total income of the community, (in Appendix V he shows figures that indicate that the rate of return on subsidies amounts frequently to 500 per cent or more per annum), (3) the legal status of using public funds for a subsidy of a private industry remains very doubtful and ambiguous (in many states it is clearly illegal to use public funds for such a purpose), (4) at the moment not enough effort is being made to locally subsidize industry, in spite of great successes in those cases where subsidies were used, (5) subsidies should be made by local governments and not by state governments, (6) economists should concentrate more on advising local governments rather than the federal government.

Moes' line of argument is based fundamentally on the assumption (sometimes explicit, sometimes implicit) that the labor force is, and should remain immobile, and that each worker has a "right" to expect to find employment in the community where he wishes to live. Such an assumption is very one-sided and it seems to ignore the fact that mobility of labor has been greatly responsible for the tremendous economic growth of our country, especially in the past century. Moes believes that industry today should move to labor instead of labor moving towards industry. Does he fully realize the long-run consequences of such a policy? Would not such a policy eventually lead

to all sorts of rigidities in our industrial structure and would it not result in an inefficient allocation of resources? Moes never considers the possibility that subsidizing geographical and occupational mobility of labor (as it is done with such a great success in some Scandinavian countries) could lead, maybe, to better results than the subsidizing of industry.

There is one omission in his book that is rather puzzling. Although most of the discussion centers on the South and most of his examples are taken from the South, the question of the racial problem is never raised, and the word Negro is not mentioned even once. Surely, Moes should be aware that a great deal of the economic backwardness and lack of industrialization in the South results to a large extent from racial tensions, and from a social structure that is based on racial segregation and discrimination. It has been stated by so many writers that a country, or an area, in order to have economic progress has to stimulate also social reforms. Moes chose, however, to ignore this question completely.

In his introductory remarks Moes mentions that in spite of the fact that he will discuss examples primarily from the South, he believes, nevertheless, that his conclusions would apply also to the problems of unemployment or underemployment in undeveloped countries in Asia and Africa. This is a rather bold statement, and it would be most interesting if Moes had pursued this question further. Unfortunately no mention of it is made in the latter part of the book. In the opinion of his reviewer, the problems of those undeveloped countries are frequently of a totally different nature than the problem of the backwardness of the South. It is most doubtful that local subsidies would help very much in Asia or in Africa.

In conclusion, Moes believes that local subsidies are politically feasible, socially desirable, and economically advantageous, and should be employed on a larger scale than they have been so far. Being a strong believer in a free enterprise system, Moes is against any effort to subsidize industry on the federal or state level; he is also very doubtful about the benefits that the minimum wage law or labor unions may bring. He is all in favor of keeping the wage differential between the South and the North as wide as possible.

Moes provides an excellent documentation for his statements, especially for opinions that are critical of his views; there is an abundance of footnotes, and the bibliography and index are very good indeed. Even if one does not accept all of Moes' assertions, one has to admit that he has written an interesting book on a very controversial subject, and has made a valuable contribution to a somewhat unexplored field of economics and political science. His courage in stating views that are contrary to generally accepted opinions has to be admired.

ANDRE SIMMONS

University of Nevada

Economia d' azienda. By PIETRO ONIDA. Turin: UTET, 1960. Pp. xx, 790.

This is the ninth in a series of 20 volumes in process of publication under the joint direction of Professor Gustavo Del Vecchio of the University of Bologna and Professor Celestino Arena of the University of Rome. The completed series, entitled *Trattato Italiano di Economia*, is intended to consti-

tute an integrated treatment of all the fields of economics. In *Economia d'azienda*, Professor Pietro Onida was assigned the task of synthesizing the abstract theory of the firm with the techniques of business administration: admittedly an ambitious undertaking.

Economia d'azienda is a fairly complete survey of business administration divided into two parts. Part I, consisting of three lengthy chapters and taking up well over one half of the work, is primarily descriptive in nature and deals with the normative aspects of the organization and administration of the firm. In Part II, consisting of six chapters, the author proposes to analyze the economics of the firm in terms of "quantitative accounting and statistical measurements."

Every firm is faced with the problem of decision-making based upon the alternative choices with which it is confronted. This proposition is stated as a fact and constitutes the basic assumption upon which the entire analysis rests. The principle of alternative choices of action is developed in the first chapter which concerns itself with the problem of means and ends. Here we find that the firm is a continuum in time and space independent of its components at any instant of time. The firm, according to Onida, is more than the sum of its parts. The components of the firm, which taken all together constitute the entrepreneurial function, consist of the administrative personnel, the labor force, the financial structure of the firm, the inputs and outputs as well as the legal form of organization. The author insists that every aspect of the business enterprise must be analyzed as a part of the whole, which is both quantitatively and qualitatively different from the sum of the parts. In his own words, "it is a fruitless pretension to attempt the study of the economic significance of administrative decisions and operations while ignoring the firm as a complex, dynamic, economic entity." Therefore, we are told that we cannot hold constant all other factors except the one under observation, since any change which takes place in any one of the factors enumerated previously, must of necessity involve changes in all the constituent elements of the firm. The method of partial analysis gives erroneous results. "When a number of factors, mutually complementary, produce a given total product, . . . it is not possible to determine the portion of [the total] product which is specifically attributable . . . to each factor" (p. 79). Therefore the sum of the marginal products does not consume the total product. This is based on the assumption that the factors of production, which are defined very broadly and inclusively, are heterogeneous and the production function does not show constant returns to scale. These assumptions, however, are not explicitly stated as such, except that the author makes constant reference throughout the work to the heterogeneity of the firm and occasional references to increasing and decreasing costs as scale changes occur within the firm. The author deals now with the short run, now with the long run, blending the two together as he goes along, as a result of which the analysis is anything but rigorous. At any rate, the principle of marginal productivity is conveniently disposed of on the grounds of the statement cited above. This would appear all the more puzzling in the light of the proposal to apply the principle of alternative choices to every decision-making problem with which the firm is

confronted, for certainly we would expect that there is a maximization problem in the sales decision, for example, a cost-minimization productivity-maximization problem in the input-output decision, and in terms of financial structure, some kind of target optimum. Relax, dear reader; for the firm of "concrete reality" there is no maximization and no minimization. There are merely convenient targets which the firm shoots at, and apparently, hopes sometimes to hit. Perhaps this explains why the principle of alternative choices is expressed as the "principle of the convenient choices of the firm." To this reader it is not clear what, if anything, is being maximized or what this "convenience" really is.

Furthermore, in view of the stated assumption that a decision of the firm to make a change in one of its factors, e.g., labor, necessitates making decisions respecting changes in all the other factors, we would expect the author to apply a general equilibrium analysis to the solution of this problem. But since we are dealing with the "concrete reality" and not the firm of "theoretical abstractions," the business enterprise is never in an equilibrium position nor does it ever tend toward an equilibrium position. As an attempt to apply the tool kit of economic theory to the analysis of administrative and organizational problems, *Economia d' Azienda* fails to do the job.

A Study in Econometrics: The Demand for Electricity in the United States.

By FRANKLIN M. FISHER IN ASSOCIATION WITH CARL KAYSSEN. Amsterdam: North-Holland Publishing Company, 1962. Pp. xvi, 190. \$5.00.

This study, undertaken for the General Electric Corporation, was "designed to show what modern econometric methods could contribute to the understanding of the forces shaping the demand for electricity." Demand for electricity is studied in four parts, namely, short- and long-run household demand and industry demand with constant and changing technology. For household demand, annual data by states, 1934-41 and 1947-56, are employed while for industry demand, cross-section data by states for two-digit manufacturing industries, 1947 and 1956, and for extractive industries, 1954, serve as inputs. Multiple regression and covariance analysis are the main techniques employed.

The findings, indicated in part below, represent a rich and imaginative harvest. However they are put forward in a highly qualified and tentative manner because the authors are keenly aware of and comment cogently on data deficiencies, aggregation problems, estimation problems, and possible inadequacies of the models they estimate. Nevertheless, it is this reviewer's opinion that the study will be an essential point of departure for further work on the demand for electricity.

Short-run household demand, conceived as demand for electricity holding constant the stock of electricity-using equipment, is found to be characterized

by (a) price elasticities close to zero for "older" and more "mature" states and much higher, though less than one, for "younger" states and (b) income elasticities well below one, positively correlated with degree of urbanization and zero or negative for rural states. On the other hand, household long-run demand, the determinants of which are identified with factors determining the demand for electricity-using equipment (annual estimates of consumers' stocks of seven major appliances by state, 1944-57, are presented and discussed in Chapter 2), is found to depend not on the price of electricity but mainly on current income, long-run income (Friedman's permanent income series), number of wired households, population, other demographic variables, and to a small extent, on the prices of appliances. The main conclusions drawn from these results are that as all states mature, short-run demand will become even less sensitive to the price of electricity than it now is and more sensitive to income. As regards long-run demand, "The unimportance, in general, of price of electricity and prices of appliances means that substitution effects which might sustain a more rapid growth [of electricity demand] are unimportant."

Analysis of cross-section data for 1956 with observations by industry and state, yields an upper limit to the price elasticity of industrial demand which "is somewhat greater than unity in six of the ten industries (highest 2.6, for the chemicals industry), unity or less in two more and zero in the remaining two. . . ." Similar results are obtained for extractive industries. "Altogether, there is reason to expect a fairly high degree of sensitivity to electricity price in industrial demand given the technology of 1956."

A study of changes in electricity input coefficients for 1947 and 1956, demonstrated that industries in which the cost of electric power is a high proportion of total costs experienced smaller percentage increases in their coefficients than did industries for which electric power costs were less important. With allowance made for the effects of a fall in the price of electricity, the same tendency is noted; however, whereas without the correction 17 of 20 industries showed an increase in electricity input coefficients, the correction resulted in just 5 of 10 industries showing an increase. It is then concluded that "technological change probably acted neutrally or increased the importance of electricity—the quantity of electricity consumed per unit of output—in this period."

Some points which may deserve attention in future work follow. The Fisher-Kaysen short-run household demand function has electricity consumption dependent on current income, price of electricity, and the total stock of electricity-using equipment. Since no data are available for the stock variable, it is assumed that its first differenced logarithm is a constant, that is that the stock grows at a constant percentage rate. Thus the short-run results are critically dependent on, among other things, the appropriateness of an assumed constant growth rate and the use of current income. To the extent that departures from a constant growth rate for the stock exist, either in terms of short-run fluctuations which are correlated with income and/or price or in terms of an incorrect specification of the underlying trend function, a source of bias is present. Moreover, use of current income rather than "normal" or "permanent" income *may* tend to bias income elasticities downward, with

variable income states (probably rural states) having the largest downward bias. Could this account for the observed zero or negative income elasticities obtained for rural states? Or should we accept the authors' hypotheses that for rural states income increases (decreases) lead to more (fewer) activities outside the home and more (less) out-of-state migration and hence less (more) electricity consumption? Further, in connection with long-run appliance demand, consideration should be given to possible biases, particularly downward ones arising from the use of appliances' wholesale rather than retail prices (data for the latter were not available). Lastly, the authors' reservations and dissatisfactions with the Neyman-Pearson system of inference, which is dogma for many practicing econometricians, as well as their excellent treatment of many other econometric issues, deserve close attention and study.

In conclusion, Fisher and Kaysen, in a workmanlike fashion and with econometric sophistication, present an intriguing exploration of many aspects of the demand for electricity. It seems unquestionable that this work will be required reading for anyone who wishes to discuss the demand for electricity and the many public and private issues involving it in an informed and up-to-date manner.

ARNOLD ZELLNER

University of Wisconsin

Pricing Power and the Public Interest. By GARDNER C. MEANS. New York: Harper & Bros., 1962. Pp. xxi, 359. \$7.50.

In this book, based largely on the steel industry, Means advances the bold thesis that large corporations should be considered semipublic institutions whose management would be rewarded by liberal bonuses based upon "economic performance in the public interest." Standards would give only limited recognition to the attainment of profits and would be established by accountants, engineers, economists and professional management consultants. The book is obviously directed to an informed lay audience but professional economists can read it with profit without accepting all the conclusions or the proposed remedies.

The first 150 pages are given to an analysis of steel pricing from 1942 to 1958 in which the author concludes that the major responsibility for the rise in steel prices, particularly after 1953, must rest with the industry rather than with labor. Prices in the industry, as well as in other industries, are assumed to be administered, but unlike many other critics, Means sees little to be gained and much to be lost by the atomization of the industry. Marginalism is thought to be inapplicable and target pricing as depicted by Lanzillotti and others is assumed to be normal. Target pricing is not regarded as undesirable but is thought to be necessary administratively and desirable if coupled with the cost of capital. In other words, the target price would include a mark-up limited to an amount which would give the firm a rate of return on its capital equivalent to the cost of that capital for some relevant period.

Management motivated by the objective of balancing the best interests of stockholders, employees, consumers and the general public is accepted if not as a fact at least as an emerging practice that has hopeful overtones. The di-

forcement of ownership and control of corporate enterprise is pushed to what Means regards as its logical end where the rewards of enterprise will go to management through liberal, tax-exempt bonuses rather than to stockholders. Stockholders would be restricted to returns equivalent to the cost of capital computed in somewhat the same way as they are for purposes of public utility regulation.

Means combines in striking and original fashion a number of institutions into a suggested pattern of industrial self government. This is an outstanding achievement. The difficulties of applying the cost of capital approach to the determination of the target rate of return may have been underestimated and a disservice is done to the thesis by linking the steel industry to the utility industry. The cost of capital for regulatory purposes can be broadly defined as a rate of profit sufficient to maintain the market value of the utility's securities equal to the amount invested. Certainly it is not an unreasonable standard. In the period from 1942 to 1954 steel stocks generally sold at prices far below book values and the application of cost-of-capital principles would have resulted in increased prices and profits rather than the converse. In the period from 1954 to 1958 steel stocks sold at premiums over book value, but not to the extent that gas and electric utility stocks did and regulation as practiced would have raised further the prices of an industry already presumed to be contributing to inflation.

Such relationships may or may not be unavoidable snares for the unwary in the determination of some practicable concept of the cost of capital, but if this pitfall is avoided there are a hundred more to entrap the administrator. To what extent does inflation, or deflation, contribute to the cost of capital? How is the factor of uncertainty, in Knight's use of the term, to be evaluated to say nothing of the more ordinary run of risks? The problem is not made easier by the mutual contribution of both management and regulation to the creation of these self-same risks. Is Means justified in his more or less casual assignment of a large portion of profits to management? Even more basic is the problem of the allocation between customers and stockholders of the costs of excess capacity in periods of slack demand. Under regulation these costs would be born in large measure by the customers; under conditions of competition they would be born by the stockholders. Would it be feasible to raise prices by administrative fiat in periods of falling demand to maintain earnings equivalent to the cost of capital?

If it is conceded that regulation has worked with a degree of effectiveness does it follow that the methods, concepts and objectives can be transferred in any significant manner from a limited segment of the economy to an economy of large corporation which together make up the bulk of the private enterprise system? On an administrative level can accountants, engineers, managers and economists be found upon whose judgment we can rely? How long would it be before the lawyers took over? Can we expect the emergence of any real standards of "economic performance in the public interest" when these same standards have been subject to controversy for almost three quarters of a century of the Sherman Act?

Such reservations as these are not necessarily fatal and in such a book as

this must be proportional in number to the originality and significance of its content. The book is more than thought provoking; it is an outstanding contribution and ahead of its time. It may well set in motion forces that will ultimately benefit our society. Those of us, who like Means, hope for the development of a spirit of public motivation in corporate enterprise, will hope that the obstacles will not be insurmountable.

E. W. CLEMENS

University of Maryland

Antitrust and the Changing Corporation. By WILLIAM LEE BALDWIN. Durham: Duke University Press, 1961. Pp. vi, 307. \$8.75.

This work, according to its author, attempts to record the viewpoints towards the large firm in the American economy as expressed in the "literature, public debate, and legal developments since the end of the 19th century, with emphasis on the influence of economists upon policy makers and the courts." Such a review, in Mr. Baldwin's opinion, makes possible an appraisal of the "usefulness of present-day economics as a guide to proper enforcement of those portions of the nation's antitrust laws which deal with the large business organization."

The work is organized into seven chapters, the last containing the author's conclusions. Essentially, these chapters review the literature relating to the large corporation in the pre-first World War period (Ch. 1); in the period between the first World War and the depression (Ch. 2); in the 30's and during the second World War (Ch. 3); and during the postwar period (Ch. 4, 5 and 6).

Chapters 1 and 2 contain fairly complete summaries of the literature of the time; while they add little to existing knowledge, and in fact often represent summaries of other students' analyses of the primary source materials,¹ there is little to which one would take exception. Thus, for the scholar wishing to refresh himself on the early arguments concerning the economies to be realized from the trust movement, Baldwin's summaries of the works of Eliot Jones, A. S. Dewing and Shaw Livermore might be convenient.

In Chapter 3 Baldwin begins to interject into his summaries various questionable statements of opinion about the value of the works examined. The pioneering study of Messrs. Berle and Means (*The Modern Corporation and Private Property*, 1932) is described as one which, while popularizing statistical measures which served as models for later empirical studies, "reflected near-hysteria" (p. 77); Clair Wilcox's T.N.E.C. Monograph 21 is described as "a brief and clear exposition of various market categories recognized in price theory, despite a barrage of terms such as 'oligoposony' and 'duoposony' and his somewhat pedantic distinctions between pure and perfect competition and between imperfect and monopolistic competition" (p. 103). In fact—perhaps because of his feeling that, "Many of the scholars who wrote

¹ Baldwin's discussion of the early development of the antitrust laws admittedly draws heavily on those of J. B. Clark, Oswald Knauth, L. Letwin and Hans B. Thorelli (see page 25). References to senatorial debates on the Sherman Act are generally not to the transcript of those debates but to citations of those debates by other authors.

the T.N.E.C. Monographs evinced a lack of faith in the competitive process"—Baldwin presents rather harsh judgments of the work of the Committee and of its monograph authors. The authors of Monograph 22 (L. L. Lorwin, J. N. Blair, and Ruth Aull) are chastized for not attempting to estimate quantitatively the degree to which technological unemployment was responsible for the depression (p. 106); the studies of Walton Hamilton (Monograph 31) and Myron Watkins (Monograph 13) are characterized in the following language (p. 108):

Nowhere is there any indication that there might be a necessity for the stimulation or encouragement of research activities, or that the problem was anything other than that of effectively utilizing a stream of inventiveness whose source was not investigated but whose continued abundance was presumed unless it was choked off by monopoly.

And T. J. Kreps' Monograph 7 (*Measurement of the Social Performance of Business*) is criticized for containing no effort at empirical validation of the observation that competitive industries are generally characterized by fuller utilization of capacity than are concentrated industries (p. 113). In sum, the author concludes that "the indictments made [by the T.N.E.C.] were weak and were unsubstantiated by the voluminous statistical material presented" (p. 110). Further, the economists working with the T.N.E.C. are accused of placing "only minor emphasis on the product-market effects of monopoly," while devoting much attention to the role of big business in the depression of the period (p. 110).

In this reviewer's judgment Baldwin's attacks are not well-founded. It is easy to attack Kreps, for example, for not providing empirical validation of his thesis, Wilcox for attempting to make "somewhat pedantic distinctions," and Berle and Means for "near-hysteria." Yet, this reviewer would be inclined to wonder *how*, almost a quarter of a century after Kreps' work appeared, Baldwin would go about empirical validation of the thesis that concentrated industries, e.g., steel, operate at lower rates of capacity than do nonconcentrated industries, e.g., textiles. And he would point out that the distinctions made by Wilcox were apparently not sufficiently sharp to satisfy other critics.²

It is also unclear how the work of the T.N.E.C. can be criticized for placing "minor emphasis on the product-market effects of monopoly" when the thrust of the analysis of the patent problem, for example, was directed precisely at the impact of the patent laws on product markets. Finally, dismissal of the results of the T.N.E.C. as "a failure of economic analysis to influence public policy" (p. 114) seems unwarranted. The Committee's investigations of the oil industry certainly affected subsequent policy toward the integrated companies and resulted in having crude oil pipelines declared common carriers, a move which increased the level of competition in the gasoline markets in the Midwest. Also, the problem of the cartelization of the glass container industry by the Hartford Empire Company was dramatized, as an almost direct result of which the Hartford Empire case was instituted; and Monograph 43 (*The Motion Picture Industry—Pattern of Control*) pointed

² See G. J. Stigler, "The Extent and Bases of Monopoly," *Am. Econ. Rev.*, No. 2, Part 2, June 1942, 32 (Pt. 2), 3, n. 5.

to the problems created by block-booking of motion pictures, problems solved shortly after the Second World War by a series of antitrust cases.

One final criticism is, perhaps, in order. There are a few important omissions from Baldwin's survey of the literature which should be noted. Despite apparent concurrence in their conclusions, Baldwin fails to mention the study of the antitrust laws by Dirlam and Kahn;³ his discussions of economists' contribution to the formulation of antitrust policy and to the ascertainment of the impact of the laws neglects Simon Whitney's two-volume study;⁴ the discussion of Galbraith's concept of countervailing power—described as "the most significant and influential work to be produced in the postwar period in this area of re-examination of the operation of a competitive mechanism" (p. 167) nowhere considers the points raised by Whitney in his review.⁵ And, returning once more to Baldwin's evaluation of the Temporary National Economic Committee, no citation is provided to the *Supplement* to the June 1942 *American Economic Review* dealing with the work of the Committee.⁶

National Transportation Policy; Report of the Special Study Group on Transportation Policies in the United States. U. S. Senate, Committee on Commerce, Report No. 445, 87th Congress, 1st Session. Washington: Superintendent of Documents, 1961. Pp. 732. \$2.00.

This report is one of the latest of the ever-growing series of studies of transportation problems in the United States. The document has become known as the Doyle Report, after Major General John P. Doyle, U.S.A.F., retired, director of the special study group which prepared it. Over 20 professional staff members, an advisory council, and *ad hoc* committees of representatives of various transport trade associations participated in the study group.

Appearing first on the Senate's list of problems to be examined in the study is "the need for regulation of transportation under present-day conditions and, if there is a need for regulation, the type and character of that regulation." The Doyle Report's conclusions are controversial and clash directly with those reached in another recent official study.

... exception is taken here to the emphasis which is placed in the Department of Commerce recommendations on freedom to compete [*Federal Transportation Policy and Program*, Washington 1960]. For if rate policy stresses freedom to compete a [sic] serious paradox is created with regard to the broad long-range objectives of national transportation policy. How

can freedom to compete in ratemaking be reconciled with the objective of insuring a proper structure for the transportation industry? (P. 432.)

Frequent mention of "destructive" and "cutthroat" competition throughout the report emphasizes the conclusion that increased control rather than increased competition should be relied upon to allocate transport resources. The argument for extending control is based upon the prospects of further decline in the relative position of common carriers in the nation's transportation network. "We frankly face a shift from a private public carrier-based transport system to a private and exempt carrier-based system along with the prospect of Government-owned railroad industry" (p. 85). Policies must be adopted to reverse this trend, for "ownership or operation of carriers by the Federal Government is to be avoided," (p. 32) and "all evidence points to the national necessity of preserving common carriage as the only means of providing the general transportation service needed by all" (p. 33).

With these assumptions as background, the report examines many of the current problems of the transport industry and its regulation. It recommends a major overhaul of federal machinery affecting transport with a single regulatory commission to replace the Civil Aeronautics Board, Interstate Commerce Commission, and Federal Maritime Board; establishment of a cabinet-level Department of Transportation; and all federal transport laws as uniform as possible and in a single statute. Much more important to resource allocation is the proposal that the regulatory agency require rates to be set at long-run marginal cost, a cost concept having "a well-defined technical economic meaning" (p. 410). Other matters receiving detailed treatment include the transportation system's role in national defense, private and exempt carriage, railroad passenger service, urban transport, transport needs of rural areas, railroad consolidation, common ownership of different modes of transport, and the freight car shortage.

Unfortunately, and perhaps unavoidably, the report leaves many questions unanswered. If a present trend toward government ownership of railroads is identified, is it possible that it is later than the authors think, and, therefore, that preparation should be made for such an eventuality? Does the long run marginal cost pricing formula yield sufficiently clear welfare implications to warrant its use as *the* guide by which transport price should be set? Why abhor government ownership or operation of railroads and yet propose a long run marginal cost criterion which would eliminate managerial discretion regarding price? Without placing restrictions on the right to private transport, how will it be possible to develop regulation which will permit common carriers to stem the tide of private carriage, and at the same time avoid "ruinous" competition? Can common carriers win the battle against private transport without becoming so highly specialized that they will no longer be able to provide transport services required by small shippers? Would a super-commission dealing with all transport merely compound the present defects of commission regulation?

The mass of descriptive and statistical material on the myriad features of U.S. transportation scattered throughout the Doyle Report's 732 pages makes it a useful reference work. (It is a shame that the report is not indexed, though there is a detailed table of contents and an excellent summary chapter.) The

authors' outspoken positions on many issues are thought-provoking and make familiarity with this work a must for those interested in transport policy.

LARKIN WARNER

Oklahoma State University

Horizontale Karteller. By PREBEN MUNTHE. Oslo: Universitetsforlaget, 1961. Pp. 172.

In this stimulating book, Professor Munthe contributes to the understanding of the price and output decisions of cartels and of the behavior of member firms. The author is searching for tools with which to analyze production and price problems as he sees them, and in the process he experiments with an array of microeconomic models ranging from perfect competition to monopoly.

Since Munthe is interested in actual markets he adjusts his assumptions and uses his kit of analytical tools to solve the problems as they arise. A few of the market situations are peculiar to Norway. The discussion of what he calls "decentralized" markets is interesting as an explanation of practices in the fishing industry and agriculture in Norway. The objective of each producer is assumed to be to maximize profits in the short run. The cartel as a monopsony generally will not control the quantities supplied by each producer. If there is extensive competition from the cartel's customers, the price will be the same with or without a cartel. However, there is not necessarily much competition on the demand side. For instance, the various buyers may utilize the product for different purposes or the buyers may be few and far apart geographically. Under such conditions the cartel acts as a central export agency and may be able to establish a discriminating monopoly. A bilateral monopoly may also develop between the export agency and the foreign buyer, in which case price will depend upon the bargaining strength of each party.

In a later chapter Munthe analyzes whether a duopolist or oligopolist will try to maximize profits over a short or a long period of time. In this section he draws on papers published by Hicks, Hahn, Lydall and Ahmad in *Oxford Economic Papers* between 1954 and 1958. While in any type of business organization there is the tendency to stress the near future more than the distant future, there is more stress on the future build-up of profits in the typical duopoly or oligopoly market than in the "decentralized" market.

The last chapter, titled "Partial Cartels," deals with collusive agreements which may cover selling price or market allocation but leaves open rivalry on matters not covered. In effect, the collusive agreement covering selling price will turn into a full cartel including not only uniform price, but output quotas, market allocation, product development and other matters of concern to the industry. The formally organized full cartel is rare, however, because of anti-trust legislation.

From the standpoints of method and conciseness of presentation, this is one of the best studies in the application of microeconomic analysis to a series of price and output problems which has come to this reviewer's attention.

FINN B. JENSEN

Lehigh University

Land Economics; Agricultural Economics; Economic Geography; Housing

Tratado de economía agrícola. By EDMUNDO FLORES. Mexico: Fondo de Cultura Económica, 1961. Pp. 442. Mex. \$40.

The author, professor of agricultural economics at the Escuela Nacional de Economía Agrícola at Chapingo, Mexico, has written this text for Latin American students in the belief that agricultural development is a necessary condition for further economic growth in practically all Latin American countries and that available literature in Spanish is both scarce and of poor quality. His main criticism is that most Latin American authors unthinkingly attempt to follow the theories, attitudes and prejudices of European and North American economists despite their manifest unsuitability for analyzing the economic problems of Latin American societies. In characteristically unmutated tones, Flores marks off the grounds for Latin rejection of prevailing Anglo-Saxon economic thought patterns—which should interest American economists.

The work is a rather strange compendium grouped in four books of from three to seven chapters each. The first book contains chapters dealing with agriculture, economics, and development. About 75 pages are devoted to an introduction to the literature on economic growth (Myrdal, Nurkse, Rostow, Marx, Gerschenkron) and the relation between agricultural development and economic growth. Perhaps by way of demonstrating the justice of his strictures against neoclassical theory, 45 pages are devoted to a lucid translation of the ideas of demand and supply schedules, elasticities, the production and consumption functions, the cobweb theorem, the terms of trade between producers of primary and secondary products, parity prices, the national distribution of income and the formation of capital. Stigler, Walras, Knight, Marshall, Schumpeter and Schultz constitute a small sample of the authors cited. The translation of neoclassical economic theory from English into Spanish is like separating base metal and gold in an alloy. For us the gold consists in the value judgments embedded in the original constructs but it disappears when the English words are translated into a language whose value connotations are very different. It is this which encourages Latin Americans to think that *gringos* confuse gold with dross.

Book 2 (165 pages) is devoted to resources and space: to making such points as that the use to which resources are put is conditioned both by the distribution of ownership of capital and the distribution of income; to delineating the location of agricultural production in Mexico; to analyzing urban growth, discussing the milkshed of the Federal District, and delving into the economics of forestry.

It is Book 3 which ought to be made available in English. The subject is agrarian reform. The destruction of the indigenous society by the conquistadores; the development of the *latifundio*; the odious role of the foreign-controlled plantation; and the invention of the *Ejido* are chronicled with honest fervor. One is reminded that Latins do not find it necessary to pretend that

their academic writing is above politics. In Chapter 14, "The Plantation," Flores argues

One cannot suppose thus that the propaganda of the United Fruit is destined to improve relations between the Company and the people who produce bananas. Rather its purpose is to reaffirm the confidence of the North American public in its institutions and business. Thus each time that United Fruit has difficulties in its colonial dependencies one can be sure that public opinion in the United States will absolve the Company by virtue of the curious but sure psychological mechanism of attributing frictions between the Company and the country involved not as problems of salaries, prices, concessions and so on, but as a conspiracy fomented by Communists . . . Under these conditions, any political, economic or social reform, however mild, awakens fears and is immediately considered as a dangerous precedent.

In accordance with this form of manipulating North American public opinion and of interpreting the news, any policy destined to remove the Latin American people from the humiliating state of poverty in which they live under the colonial regimes of monoculture, will have to be postponed until the North Americans win the cold war—or lose it. Thus as long as that day does not arrive, the security of the continent and the security of United Fruit are the same thing.

The message for Latin American students, clearly set out in Book 4, is that Mexico, Bolivia and Cuba have shown the way. It is to be hoped that other countries can consolidate their gains from revolution more rapidly. Mexico, it is argued, can now accelerate her rate of growth by rapidly completing her agrarian reform, consolidating hopelessly small properties, forcing industrialization and reducing the percentage of the labor force in agriculture, making increased use of foreign trade, stepping up research, technical education and expanding agricultural extension work.

Today, the factor responsible for the poverty of the majority of Mexicans—notwithstanding the spectacular rates of development—is the squandering of human resources, which is manifested principally by chronic unemployment for a considerable sector of the population, by a great mobility of labor, and by the very low levels of productivity in the majority of activities.

This critical problem must be conceived as a function of the level of employment and income. Seen in this way, it is the responsibility of the State to see that the unemployed have work and are paid a minimum income sufficient to satisfy their basic necessities for food, shelter, clothing, and education. As a counterpart of this policy of redistribution and as a fundamental requisite to sustain it, it is also the responsibility of the State to introduce those innovations which by augmenting the efficiency and capacity of the productive apparatus, redound in an increasing rate of growth of the national income.

To secure the foregoing, it is necessary to put into play all the resources of planning, both at the macroeconomic and at the regional level. Public and private investment, fiscal and monetary policy, foreign trade policy,

and the preparation of technicians at all levels must be reoriented and coordinated to obtain the highest possible rates of capital formation.

One comes away with the distinct feeling that—one way or another—Professor Flores is going to be instructing the *gringos* for a long time to come.

Labor Economics

Labor Economics. By CHESTER A. MORGAN. Homewood, Illinois: The Dorsey Press, Inc. 1962. Pp. xii, 657. \$8.00.

Professor Morgan presents a frankly institutional text book for what he sees as a "one-semester course in labor economics or labor problems." It would be equally good for a one-quarter course. Although he assumes that his organization of the material is "somewhat unorthodox," it seems to fit the traditional pattern. Without undue verbiage he presents the major topics typical of post Wagner-Act labor economics text books. Writers in the labor economics field seem unaware of the considerable overlap in text books for Labor and Personnel courses. Workers in the labor economics vineyard seem relatively untouched by the human relations approach but text writers in the managerial traditions seem, recently, to be markedly influenced by the inter-disciplinary concepts from the burgeoning area of the behavioral sciences.

The Morgan text groups 20 chapters into five parts: (I) Introductory; (II) Economic Problems of the Industrial Labor Market; (III) Resulting Institutional Developments; (IV) Political and Legislative Outgrowths; and (V) Conclusions. Each Part has a lucid and succinct preface and each chapter makes transition easy with a summary. Good writing and editing contribute to possibly good reception by the student.

Part I emphasizes semantics and develops the twin concepts of labor force and labor markets. The major theme and continuity thread which ties the textual fabric together is the influence of industrialization and mechanization upon individual wage earners and upon labor-management relationships. Here again there is an excellent opportunity for an avowed institutionalist to enlarge upon a real understanding of men-at-work in primary work groups. Some industrial sociologists may be stealing a march on their economist confreres in getting at grass roots factors in behavior.

Part II begins with the typical parade of wage theories. This effort seems unrealistically connected with the discussion on short-run wage determination and wage trends. Three chapters and 100 pages of this section are given over to wage problems yet only a few pages are devoted to the modern and much used job-evaluation methods of determining relative job-rates. Realism demands more interdisciplinary interaction of scholars.

The remaining five chapters of the section discuss: "Working hours" and working conditions and various forms of insecurities such as: unemployment, industrial accidents and disease and problems of aging workers. These problems are ably done in Morgan's own style of articulating. Sandwiched be-

tween discussions on these brands of employee insecurity is a unique contribution on Employment Theory. The whole continuum of explanations on unemployment and variations in full employment are clearly and briefly made. Then, in approximately 12 pages, there is a lucid summarization of the Keynesian approach.

Part III analyzes "dominant theories of labor movements" and then uses only three chapters to trace the growth of labor organizations in the United States and to explain Union Structure and Government. Here again there is a missed opportunity to make use of developing ideas on workers' needs other than economic. No real effort is made to show changing leadership influences in labor organizations including changing concepts about democratic forces at various levels of union organization. If industrialization has brought big unions into being, a student may wonder how members of unions overcome autocracy and misleadership.

In this section a separate chapter leans heavily on Bonnett in showing the growth and influence of Employer Bargaining Associations. Following this is a description and analysis of the "internal activities, tactics and devices of labor unions and employers (associations)" as agents in a dynamic brand of collective bargaining. Both Management Prerogatives and Union Rights get a going over as elements of institutional security requiring industrial government.

In Part IV the author shows excellent descriptive skill in tracing the ramifications of the external activities of bargaining agents. These activities are seen as political, legislative and public relational. The objectives of managerial and union leaders seem to tie into the economic consequences of industrialization without considering the research findings of the behavioral scientists which discuss the motivational influences of leaders trying to meet the noneconomic needs of both followers and leaders.

The meat of this part consists of two chapters on the advent and growth of labor relations law and the substantive labor law subsumed under such headings as: wages, hours, working conditions, economic security and the protection of unorganized minorities.

In the concluding Part, a single chapter serves as a vehicle for assessing the roles of each of the labor market institutions: labor organizations, employers and their associations, and the central government. Attention is centered on over-all economic consequences of these institutions with brief mention of the crucial key-problem of interinstitutional cooperation in the production process.

Morgan has tried to achieve the "goal of a relatively continuous story." He does this with a fluid style but fails to utilize the dramatic possibilities of modern ideas from organization theories and the men-at-work behaviorists.

ALBERT T. HELBING

Montana State University

Trade Unions in a Free Society. By B. C. ROBERTS. London: Institute of Economic Affairs, Hutchinson of London, 1962. Pp. 206. 30s.

This small volume by a well-known British expert combines his two earlier

books on British and American unionism. The two parts are quite independent, without any concluding comparative discussion. In the British part one wishes for more explicit comparison, as points of likeness or difference occur to the reader. The American section has more reference to British and other European experience. The analysis is well-informed and its broad perspective offers new insights. The assumption is that "free trade unionism is an essential feature of a free society, and that whenever it is possible and consistent with modern needs and equity, it is better to leave issues of social conflict to the autonomous solution of the parties than to administrative or legal regulation." Part I, on unions in Britain, includes chapters on the principles at stake, trade unions and wage problems, industrial relations, politics, and union structure and organization. Part II on the United States discusses union structure, democracy, corruption, wage bargaining and inflation, industrial relations, and politics.

Among the points of difference in British industrial relations from American are the relative absence of legal regulation of unions and collective bargaining and the lack of well-defined local rules. Collective agreements are more typically national, and are not legally enforceable contracts for definite terms. There is a growth of local bargaining, but still no wide-spread system of handling grievances as they arise, or of grievance arbitration. Shop stewards in many industries have substantial power, without being well-integrated into the union structure. As a result, large numbers of short local unauthorized strikes occur. The author recommends more attention to local problems and more effective control by the unions over shop stewards. Such changes also would make more possible the revision of out-dated attitudes towards restrictive practices.

Problems of individual rights are receiving increased attention in Britain, as in the United States. Compulsory unionism is not widespread in Britain and is not regulated by law. Rival unionism is opposed by the Trades Union Congress, which only in extreme cases will recognize a new union, breaking away from the old. Courts are showing a tendency to protect workers against expulsion or against improper election procedures. The more serious problems in the United States in these areas are recognized as having led to necessary regulation, although the author is not entirely optimistic as to the results. For Britain he suggests only that registration of unions, as a basis for legal privileges, should be granted only to unions whose rules provide adequate safeguards for members. A system of public appeal boards, similar to those in a few American unions, is recommended to British unions as a further safeguard of members' interests. He is concerned, also, lest in both countries the needs of stability so counteract the desirability of free choice of union, that the leadership is not enough subject to check by the membership.

Trade union democracy and apathy of members towards corruption or communist domination has become a matter of concern in Britain in some cases, parallel to the wider problem of corruption and undemocratic practices in some American unions. Contests in national union elections, however, are much more common in Britain than here. Excessive centralization of authority in the hands of the national officers, and lack of adequate finances and

staff for needed services, are more serious problems there. In American unionism, on the other hand, lack of contests in elections, difficulties of any effective opposition even in the most democratic union, centralization of power in national offices with their large funds, and absence of effective check by the rank and file, all raise questions. The author believes that the regulations imposed by the 1947 Labor-Management Reporting and Disclosure Act were needed and will be salutary. The problem of corruption as well as lack of democracy in so many American unions is seen as reflecting aspects of American society, and difficult to eradicate, despite efforts by the AFL-CIO and federal legislation.

On the problem of wage bargaining and inflation in both countries the author believes that excessive general demand is the major source of inflation. His studies reported elsewhere have shown that "every country which has attempted to control its inflation by means of national wage policy has failed to achieve the success for which it hoped." Obviously inflationary wage demands, however, and refusal of employers to compete by price reductions, pose problems difficult to solve, especially in view of conflicting demands for economic growth and price stability. He believes that in the United States political pressures will lead to some form of machinery for controlling the rate of wage increases, although the chances for success are slim. He suggests more adequate unemployment compensation to make some level of unemployment politically tolerable, and a higher degree of responsibility of all concerned, unions, employers, and government, if excessive inflation is to be prevented.

There is also interesting discussion of joint consultation, possibly overdone in Britain and not as effective locally as had been hoped, though the National Joint Advisory Councils have helped to maintain a healthy industrial atmosphere. For the United States the author believes that there is need to find ways for the ordinary worker to exercise a more creative role, with greater participation in local decision-making in the plants. At the national level he suggests that joint advisory councils similar to those in Britain and other European countries would enhance the prospect of improved industrial relations, in a country where industrial relations have been so marked by antagonism and conflict.

EMILY CLARK BROWN

Minneapolis, Minnesota

The Economics of Unemployment Compensation. By RICHARD A. LESTER.
Princeton: Industrial Relations Section, Princeton University, 1962.
Pp. x, 137. \$3.75.

In this stimulating monograph, Professor Lester attempts (1) to promote economic analysis in a chronically contentious area, (2) to bring to bear a measure of his own analyses on a number of outstanding issues of unemployment compensation, and (3) to recommend a program of amendments that might be acceptable to the differing parties all around.

From the standpoint of economic analysis, a system which in 1961 disbursed \$3.4 billion and collected \$2.6 billion, undeniably exerts significant

aggregative effects on the economy. No one would be inclined to argue that study of these effects is not worth while; indeed, this area has been much neglected. What may be disputable is Lester's interest in analysis as a means of enabling unemployment compensation to meet grand economic objectives, including countering the business cycle, maintaining mass purchasing power, meeting problems of new types of unemployment as they arise, and stabilizing the economy generally.

These would be truly formidable goals to attach to any social system, much less to a quasi-insurance, quasi-welfare one that has serviceably, if not too liberally, compensated partial wage loss for some 25 years to the tune of criticism from all directions. The practice, of course, is not new. It goes back to the 1930's when, in view of the then primitive state of countercyclical measures, economic objectives made good sales points for the proposed legislation. As these objectives are reiterated, the reviewer, for one, has grown somewhat dubious about looking to unemployment compensation to carry out multiple economic objectives. It may be much less distracting from more realistic goals to regard the economic effects of unemployment compensation as by-products rather than planned consequences. Moreover, what the new economy and labor force are doing to unemployment compensation seems to have become more important than the effects the other way round. A quarter of a century of experience offers little occasion for optimism that the system may yet prove a great controller of economic events.

Lester's own analyses bring out the inadequacies of unemployment compensation as an economic instrument. Since 1948, benefits have offset only 20 per cent of wage loss from total unemployment. Total benefits never exceed 2 per cent of aggregates like labor income, disposable income, or even consumption expenditures. Recession unemployment is compensated at the same rate as nonrecession unemployment, notwithstanding the teachings of business cycle theory. The patterns of quarterly net flows under the system have "unfortunate economic consequences" (p. 23). The inadequacy of benefit payments to individuals affects their buying patterns and reduces consumption. Benefits are "weak in leverage" (p. 37). Unemployment compensation is failing to meet the problems caused by a labor force composed of such diverse groups as students, married women, semi-retirees, part-time and intermittent workers, new entrants, older workers, and long-time unemployed.

On the experience-rated payroll tax—the carrier of numerous economic objectives and practically the only source of revenue for unemployment compensation—Lester finds that no more than a third of the tax is shiftable to the consumer in higher prices. Since the tax is thus not inflationary, it has not been overutilized. The long overdue rise in taxable wage base above the first \$3,000 of individual employee earnings is certified on the basis of thorough economic analysis. Nevertheless, the persuasiveness of Lester's briefs does not dispose of the need for diversification of revenue sources if noneconomic objectives are to be met.

Considering the stress on economic inadequacies, it is surprising that Lester should in the end advocate a 10-point "program for improvement" that will merely "necessitate modest changes in both federal and state laws"

(p. 124). These would include wider coverage, tightened eligibility, a mild federal benefit standard, higher taxable base, federal matching of extended benefit costs from the payroll tax, and a federal-state relief program. It is a little difficult to see how these marginal changes will suffice to turn unemployment compensation into an adequate economic instrument. They look much like the "muddy compromises" that Lester deplors at an earlier point (p. 5). Economic analysis cannot hurt the process of political compromise, but it will not sustain the assignment of high economic objectives to a system that ought to decline in significance as a many-sided, fully-complemented attack on unemployment finally gets underway. The latter would include both general economic measures for heightening effective demand and specific measures like the Area Redevelopment and Manpower Development and Training programs that are now at hand as well as others that are coming along. All these programs bespeak a shrinking role for unemployment compensation. Intent on fostering the economic role, Lester has little to say about them.

HARRY MALISOFF

Population; Welfare Programs; Consumer Economics

The Consumer in Our Economy. By DAVID HAMILTON. Boston: Houghton Mifflin Company, 1962. Pp. ix, 473. \$6.50.

Professor Hamilton's book puts consumption squarely into the field of economics as known today. If consumer economics textbooks were to be grade labeled like olives, this reviewer would put Hamilton's book in the "super-colossal" category. He offers a combination of demand theory, consumption patterns, and marketing material. He presents both "indifference" and cultural analyses of consumer behavior. Not only will the reader have the opportunity to become well informed about consumer economics but he may profit from following a first-class mind. In addition to all these virtues Hamilton is a good writer. After Samuelson, an economist has been expected to write wittily as well as accurately, at least from his colleagues' point of view. Professor Hamilton justifies this expectation.

The book consists of 14 chapters organized into four parts. The first of these has demand theory, a contrasting cultural approach, and an attempt to apply cultural observations to consumption, but it cannot be said that a new theory of consumption evolves. The next part is concerned with consumers in the market, beginning with standards of living, including family finance, aids to consumers, cooperatives, consumer pressure group (or its lack). The third part is concerned with government's relation to consumers such as resale price maintenance laws. The last section explains the Keynesian view of consumption's role in national income determination.

Courses in consumer economics are taught in many different departments in this country. A home economics specialist might want the second part expanded, but books such as Margaret G. Reid's *Consumers and the Market*, Jessie V. Coles' *The Consumer-Buyer and the Market*, and Elizabeth E.

Hoyt's *Consumption in our Society* are available no longer for current textbook use. A teacher in a liberal arts economics department would find Hamilton's book at least as useful as Cochrane and Bell's, and probably better than Bryant Phillips'. J. N. Morgan's material on family finance is good, but Hamilton includes similar material and encompasses more economics in sections 1 and 4. The obvious limitation of section 3 is that only a narrow view of the government's activities is presented. Clair Wilcox in *Public Policies Toward Business* gives a broader perspective, but his book is not otherwise adapted to a course in consumer economics.

An economist will not be disappointed in Hamilton's exposition of demand theory. He does one of the best one-chapter jobs available. Beginning with marginal utility, going on to indifference analysis, and ending with the ordinal-behaviorist approach he explains demand theory so that any student willing to do the work can understand it; nevertheless, an economist would not feel that the material had been treated superficially.

He is less successful in his effort to coordinate cultural behavior and consumption theory. In Chapter 2 where he attempts to describe human nature he is in fact describing classifications for studying it: culture, mores, status-defining role, rite. No generalizations are made about human behavior per se. Without them, however, this reviewer does not understand what is superior about a cultural approach to the economic theory of consumption.

If cultural understanding is to be used for prediction one would need to do as Veblen did and focus upon the elements of change or conflict within the culture. Hamilton refers to Veblen's "two aspects of culture," the "instinct" of workmanship and pecuniary emulation. "All of human activity is a mixture of both institutional and technological behavior" (p. 54). This is as close as he gets to generalization about human behavior upon which a theory of demand could be founded. His work should not be depreciated, however. He is making a pioneer attempt to combine the knowledge of human nature contributed by other social sciences to the need for that knowledge which gaps in economics.

Hamilton is at his best, in this reviewer's opinion, in a chapter such as "The Standard of Living and Its Measurement." What can be learned he presents, and that is a great deal.

He short-changes standardization, in this reviewer's estimation. Standards are the basis for intelligent comparison by consumers. Hamilton describes consumer-testing agencies' work, but standardization should be considered with reference to its function in a semicompetitive economy.

Hamilton's knowledge of cultures is reflected in his recognition of consumer credit's importance in our economy. Probably this book was written too early to include the "Truth in Lending" controversy publicized through Senator Douglas' committee.¹ No attention is given the role of pressure groups in keeping a multiplicity of formulas before consumers so that not only do many consumers not know how to compute the true annual interest rate, but experts do not have *one* best choice.

¹ Senator Paul Douglas' subcommittee, Senate Committee on Banking and Currency, 1st sess., on S. 1740.

If one focuses on what this book has rather than what it has not, Hamilton shows why economics of consumption is part of the economics curriculum in some universities.

Related Disciplines

Conflict and Defense: A General Theory. By KENNETH E. BOULDING. New York: Harper & Brothers, 1962. Pp. ix, 349. \$7.00.

This book is an important contribution by a distinguished economist to the growing trend toward more rigorous theoretical analysis in the social sciences other than economics. Its purpose is to analyze social conflicts, and in particular international conflicts, by means of formal analytical models derived from a large number of different disciplines, such as economics (especially utility theory and the theory of duopoly); Lewis F. Richardson's mathematical theory of arms races; mathematical ecology dealing with interaction between populations of different biological species; Kurt Lewin's and Neil E. Miller's theory of intrapersonal conflicts; and several other fields.

The author makes very skillful use of simple geometrical tools of analysis and always restates his conclusions in "literary" terms, which should make his book basically accessible also to social scientists with little mathematical background—though of course full understanding of the argument inevitably does require some mental effort by the mathematically unsophisticated. The book brings together such a wealth of material that it cannot be adequately summarized within the space available.

Fundamental to the author's theory of conflict is the distinction between shortsighted and longsighted behavior. Shortsighted behavior consists in regarding the opponent's strategy as given and choosing a strategy that is the best reply to the opponent's strategy. If both parties follow such shortsighted behavior, the result will be a conflict process more or less like a Richardsonian arms race. If this leads to an equilibrium situation at all, it will lead to what game theorists call a noncooperative equilibrium point. But in most cases both parties could do better by adopting a cooperative joint strategy, which Boulding calls longsighted behavior.

So long as the parties persist in shortsighted behavior (or so long as there is any danger that they may relapse into such behavior), the question arises whether either party could annihilate or conquer the other without committing suicide. This question is analyzed by the author's theory of viability. This is perhaps the most important technical contribution of the book. His basic model is derived from the theory of spatial competition between duopolists and is then extended to international rivalry between two countries. The essential conclusion is that different countries will retain their viability against each other if they (or their centers of gravity) are not too close to each other; if the costs of transport for military forces and equipment are sufficiently high; and if the efficiency of national military organizations is subject to strongly enough diminishing returns to scale. Up to the advent of the atomic

bomb these conditions were satisfied and so a many-nation system of international organization was a stable system. But since the availability of atomic weapons to *both* the United States and the Soviet Union no nation now has full security (viability) against her rivals; and the whole international system based on a control of armed forces by independent national governments has become intrinsically unstable. Only an international police force controlled by a supranational organization, with appropriate arrangements for international conciliation, mediation, and arbitration, can restore international stability.

Though the author draws his models from a large number of different fields, he combines them remarkably well into an integrated general theory. But the reviewer feels that at some points this integration is less than fully successful. In particular, in the discussion of the Lewin-Miller theory of intrapersonal conflict, it never becomes completely clear, e.g., why the subject's stable equilibrium position at some "optimal" distance from an ambivalent goal is unsatisfactory, in spite of the fact that according to the author's analysis it seems to correspond to the position of maximum utility. This situation cannot be satisfactorily analyzed without distinguishing between the "true" utility of the goal to the subject and its "apparent" utility often distorted by distance. The stable equilibrium point at some distance from the goal is regarded as unsatisfactory because it is implicitly assumed that the "true" maximum-utility point is either the goal itself (if the goal on the balance has positive net utility to the subject) or is a point very far away from the goal (if the goal on the balance has negative net utility)—but in neither case is the true maximum-utility point half-way in between, where the subject can neither get himself to reach out for the goal nor to give it up altogether. (In actual fact, the concept of "apparent" utility distorted by distance is touched upon by the author himself when he suggests that a bale of hay "will smell a little sweeter" to Buridan's ass when he moves closer to it (p. 82). But in later analysis no use is made of the assumption that the approach and avoidance gradients are based on gradients of "apparent" rather than "true" utility.)

Another point where the author's analysis is less than perfectly clear is his discussion of shortsighted and longsighted behavior in conflict (and in particular in duopoly) situations. It is not explained that the primary reason for shortsighted behavior (i.e., for playing a non-cooperative rather than a cooperative game) is justified mutual distrust due to the absence of agreement-enforcing mechanisms in many situations, making the establishment of law-enforcing mechanisms an essential prerequisite for longsighted behavior. Moreover, since the author makes no use of any specific bargaining model it does not become clear how the two parties can ever agree on particular terms for their cooperation.

But these are minor objections which do not affect the value of this book as a major contribution to the theory of social conflicts, and more generally as a valuable kit of tools for the social scientists working on the slowly emerging integrated interdisciplinary general theory of social behavior.

JOHN C. HARSANYI

Wayne State University

Microanalysis of Socioeconomic Systems: a Simulation Study. By G. H. ORCUTT, M. GREENBERGER, J. KORBEL, AND A. M. RIVLIN. New York: Harper and Brothers, 1961. Pp. xviii, 425. \$8.00.

This book is a progress report on continuing research on microanalysis of economic systems by means of simulation. It describes the work of several people for a three-year period. It is a difficult book to review because it is too early to evaluate the potential of simulation techniques, either in predicting economic behavior or in analysis of various hypotheses concerning economic components or aggregates. The contents of this book do not constitute an adequate basis for such an evaluation. While it cannot be denied that simulation possesses different capabilities than standard analytical methods, still the proof of the pudding lies in the eating and it is possible to get but a meagre taste at the present time. Since the stimulation techniques used were described by Orcutt in this journal recently (December, 1960), a description will not be given here.

The authors contend that traditional economic predictions based on relationships between highly aggregated economic entities are doomed to failure because they do not consider the detailed economic microstructure underlying the far-from-homogeneous aggregates. It is the authors' hope that improved predictions will result from the consideration of relationships among "fundamental decision-making units" such as individual families, firms, specific markets, etc. The possibility of using such detailed models for analysis has only come about recently and is attributable to advances in the fields of survey techniques, electronic computers, and multivariate economic analysis. The behavior of economic aggregates is to be estimated by simulating the behavior of a large number of each of various types of decision-making units. The task is tremendous. It is obvious that reality is far more complicated than any simulations that can be handled on the largest of computers. There are therefore important decisions to be made concerning what aspects of reality to incorporate in the simulation and what hypotheses to test. A slight oversight in experimental design could involve years of additional data collection. It seems inevitable that gathering of basic data specifically for use in the models must be carried out.

It is possible to aggregate the outputs of the model for purposes of comparison with data derived from other models and reality. Unfortunately, however, not many such comparisons are described, the reader being provided with only brief descriptions of the "lengthy series of tests, sensitivity experiments, and projection runs" of the demographic model which was the one in the most advanced state of development. The other models in the book include one of the labor force, one of debt and liquid asset structure, one of the demand for higher education, and one of associativeconomic system. These models have not yet been subjected to extensive testing.

The authors are candid in pointing out the possibility that their models may not be an adequate representation of reality and that the use of simulation in no way assures a more realistic model. It is the authors' belief that it is easier to introduce realism at a highly detailed rather than a highly aggregated level, although this may be extremely difficult to accomplish. For example, no matter how detailed the consideration of birthrates, the postwar

baby boom would not have been predicted. It is possible to introduce a microstructure that is too fine into a model as well as one that is too coarse. Improved analytical micro-models may be needed to provide adequate data for the simulation. Although many different cases can be simulated for different values of the input parameters, for prediction purposes it is necessary to have a knowledge of which of these values are more likely, or which are less. Without this knowledge it is not clear which of the simulations constitutes the best basis for prediction.

Two aspects of simulation that perhaps deserve more attention than they receive are the question of the statistical reliability of the output when inputs are stochastic, and the costs of making sensitivity analyses. The first of these problems is essentially ignored, although it is of great importance from both the point of view of costs and usefulness of results. With too small a number of random draws, the output could vary more because of random inputs than from changes in the value of the input parameters. Concerning sensitivity analyses, one of several suggested procedures (p. 386) was to vary parameters one at a time. Clearly the costs of such a procedure would be prohibitive.

The authors write that it is evident that "the major development and use of microanalytic models through simulation and other techniques lies in the future." They are to be commended for undertaking the difficult first steps whether or not the simulation technique fulfills all their hopes.

THOMSON M. WHITTIN

University of California
Berkeley

Economic and Social Consequences of Disarmament. United Nations' Economic and Social Council, 34th session, agenda item 5. New York: U.N. Sales Sec., Office of Conference Service, 1962. Pp. ix, 66. 75¢.

Economic Impacts of Disarmament. Washington, D.C.: U.S. Arms Control and Disarmament Agency, 1962. Pp. 28. 15¢.

A major depression would not result from disarmament in this or any country of the world, and reduced military spending would be an unqualified economic and social blessing. This conclusion was reached by two independent study groups composed of outstanding economists from many nations.

In January of 1962 the United States Arms Control and Disarmament Agency released a significant report in pamphlet form entitled "Economic Impact of Disarmament." This analysis, made under the leadership of Emile Benoit, professor of international business at Columbia University, focused its attention on the economy of the United States. A month later the U.N. Economic and Social Council published its document on "The Economic and Social Consequences of Disarmament." This report draws upon the knowledge of ten economists from as many countries including Wassily Leontief from the United States (Harvard), Oskar Lange of Poland, and V. K. Aboltin of the Soviet Academy of Science.

The United States report assumes that disarmament would be gradual and partial. It expects military spending to actually increase to approximately \$56 billion by 1965. Then, if world tensions are relaxed and workable agree-

ments are reached, our defense spending could decline by about \$38 billion over a 12-year period until we were spending only \$18 billion a year by 1977.

The time table envisaged by the U.N. study group would be much more rapid and the disarmament would be total for all countries. They estimate, at the present time, military spending amounts to \$120 billion a year, and about 50 million people are directly involved in the arms program. All of these resources would be quickly released for civilian utilization. The assumption of rapid total disarmament shows most clearly the benefits to be derived and the problems to be encountered.

Benoit in the U.S. study stresses the magnitude of the conversion in light of our complex, profit-oriented, industrial economy. Emphasis is placed on the difficulties of maintaining aggregate demand so as to prevent a depression. He discusses the possibilities of debt reduction, reduced taxes and increased disposable income, and of stepped-up public works. With advanced planning by governments, business firms, unions and private organizations there would be very little danger of an immediate depression of the economy. However, the aircraft, missile, shipbuilding and communications industries, which now receive the bulk of their orders from the Defense Department, and are concentrated in a few geographic areas, would be seriously damaged by the transition.

The U.S. committee questions the ability of the nation to maintain an acceptable level of growth without the stimulation of the research and development that now emanates from defense expenditures. Disarmament might, however, force scientists to re-examine research goals, and perhaps turn their talents to overcoming the technological obstacles to international economic growth and development.

The report confidently concludes that monetary and fiscal policies are adequate to cope with the economic problems that accompany any required level of military spending. But difficulties are apt to be encountered in overcoming political attitudes, vested interests, public positions, and institutional blocks.

The U.N. study believes that its conclusions are valid not only for the industrialized free-enterprise economies of the West, but also for the planned economies and for the underdeveloped nations. Economists from these three types of countries served on the study committee and were able to delineate unique problems their economies might encounter. The Communist nations would not face the problem of a declining aggregate demand nor of a cyclical contraction. Instead, their adjustment would be primarily one of adapting the physical production facilities from turning out war goods to civilian goods. The U.N. report was highly optimistic about the ease and speed with which this could be done in the Soviet Union, Poland, Yugoslavia and China.

The U.N. pamphlet deals extensively with the impact of disarmament on the underdeveloped economies. Not only could these nations be released from the burden of the military payroll, but they could reduce the number of men under arms. These men are apt to be better educated, more skilled, and in finer health than the population in general, and could make a significant contribution to production. In addition, many of these poorer countries now

use their scarce foreign exchange to buy the military hardware they are unable to produce domestically. These funds would be released, if disarmament were to prevail, and could be used to purchase capital goods. The one difficult problem some of these nations might face concerns the temporary loss of the market for the minerals or raw materials they now supply to the military powers for defense utilization. But, on the whole, greater benefits could accrue to the people in these low-income countries from disarmament than to those in highly developed nations.

The report by the United Nations on the consequences for the industrial private enterprise economies parallels the Benoit report for the United States. The U.N. study quotes the favorable results of Leontief's input-output analysis of disarmament and also, a similar study for England completed by J. R. N. Stone of Cambridge.

Cautious optimism characterizes the U.S. report, but the U.N. analysis unanimously, and without reservation, concludes that the transition can be smoothly made with appropriate national and international cooperation. A disarmed world of peace is visualized, with better housing for all, improved nutrition and health, more leisure, reduced tension, increased international trade and travel, and freedom from compulsory military service. In the words of the document, "The achievement of general and complete disarmament would be an unqualified blessing to all mankind."

NOTES

Honorary Members

At the meeting of the Executive Committee, March 23-24, 1962, the following distinguished economists were elected honorary members of the American Economic Association:

Dr. Raul Prebisch, Argentina
Professor Eugenio Gudín, Brazil
Professor Erich Schneider, Germany
Professor James E. Meade, England
Professor G. Ugo Papi, Italy
Professor Erik Lundberg, Sweden
Professor François Perroux, France

Journal of Economic Abstracts

The American Economic Association, with the cooperation of about thirty other economic journals (including the leading journals of a considerable number of foreign countries), is undertaking the publication of a quarterly *Journal of Economic Abstracts*. Each issue will provide abstracts in English of the articles, including review articles, contained in the current issue of each of the participating periodicals. The editor of the journal will be Arthur Smithies, of Harvard University. The first issue, which is to appear in December 1962, will be widely circulated without charge to the subscribers of the cooperating journals, including the members of the American Economic Association, the Econometric Society, and other cooperating associations. The subscription price for subsequent issues will be \$2.00 per year.

SEVENTY-FIFTH ANNUAL MEETING OF THE AMERICAN ECONOMIC ASSOCIATION

Penn-Sheraton Hotel, Pittsburgh, Pa.—December 27-29, 1962

Preliminary Announcement of the Program

Wednesday, December 26, 1962

6:00 P.M. EXECUTIVE COMMITTEE DINNER MEETING

Thursday, December 27, 1962

9:30 A.M. PRINCIPLES OF ECONOMIC POLICY, CONSISTENT AND INCONSISTENT, I. PUBLIC
POLICIES WITH RESPECT TO PRIVATE BUSINESS

Chairman: R. B. HEFLEBOWER, Northwestern University

Papers: Policy with Respect to Unregulated Industries

EWALD T. GREYER, University of California, Berkeley
Ambivalence in Public Policy Toward Regulated Industries
BEN W. LEWIS, Oberlin College

Discussants: ROBERT F. LANZILLOTTI, Michigan State University

JESSE W. MARKHAM, Princeton University

HENRY M. TREBING, Indiana University

HARVEY J. LEVIN, Hofstra College

TOPICS IN ECONOMIC THEORY (Joint Session with Econometric Society)

Chairman: OSKAR MORGENSTERN, Princeton University

THE AMERICAN ECONOMIC REVIEW

Papers: Theory and Institutions in the Study of Investment Behavior

EDWIN KUH, Massachusetts Institute of Technology

Investment: Fact and Fancy

ROBERT EISNER, Northwestern University

Capital Theory and Investment Behavior

DALE JORGENSEN, University of California, Berkeley

Discussants: CARL CHRIST, Johns Hopkins University

EDWIN MANSFIELD, Yale University

ECONOMIC DEVELOPMENT AND THE POPULATION PROBLEM

Chairman: STEPHEN ENKE, Duke University

Papers: Population Problems and European Economic Development in the Late 18th and Early 19th Centuries

JOHN HABAKKUK, Oxford University

Allocation Criteria and Population Growth

GUSTAV RANIS, Yale University

Discussants: WILLIAM PARKER, Yale University

PAUL DEMENY, Princeton University

DOUGLASS NORTH, University of Washington

MARK PERLMAN, Johns Hopkins University

2:30 P.M. PRINCIPLES OF ECONOMIC POLICY, CONSISTENT AND INCONSISTENT, II: ECONOMICS OF OUR PRESENT FARM PRICE SUPPORT POLICY (Joint Session with American Farm Economic Association)

Chairman: THEODORE W. SCHULTZ, University of Chicago

Papers: Welfare and Efficiency Implications of United States Agricultural Policy

D. GALE JOHNSON, University of Chicago

The Rationality of United States Agricultural Policies

WALTER W. WILCOX, Library of Congress

Discussants: HENDRIK S. HOUTHAKKER, Harvard University

GEORGE S. TOLLEY, North Carolina State College

JOHN A. SCHNITTKER, U.S. Department of Agriculture

INDUSTRIAL CAPACITY

Chairman: DANIEL CREAMER, National Industrial Conference Board

Papers: An Appraisal of Measures of Capacity

ALMARIN PHILLIPS, University of Virginia

Uses of Capacity Measures for Short-Run Economic Analysis

CHARLES L. SCHULTZE, Bureau of the Budget

Discussants: SOLOMON FABRICANT, New York University and National Bureau of Economic Research

DAVID LUSHER, Council of Economic Advisers

MORRIS COHEN, St. Johns University

ECONOMIC EDUCATION

Chairman: ARTHUR F. BURNS, National Bureau of Economic Research

Papers: Economic Literacy: What Role for Television?

JOHN R. COLEMAN, Carnegie Institute of Technology

The Task Force Report: A Critique

GEORGE J. STIGLER, University of Chicago

Task Force to Classroom

LEWIS E. WAGNER, University of Illinois

Discussants: FLOYD A. BOND, University of Michigan

CAMPBELL McCONNELL, University of Nebraska

8:00 P.M. PRESIDENTIAL ADDRESS

Chairman: JOHN ISE, University of Kansas*Presidential Address:* EDWARD S. MASON, Harvard University*Friday, December 28, 1962*

9:30 A.M. PRINCIPLES OF ECONOMIC POLICY, CONSISTENT AND INCONSISTENT, III: INTERNATIONAL COMMODITY STABILIZATION

Chairman: HERBERT STEIN, Committee for Economic Development*Papers:* Problems of International Commodity Stabilization

BORIS C. SWERLING, Board of Governors, Federal Reserve System

International Commodity Stabilization Schemes and the Export Problems of Developing Countries

RAYMOND F. MIKESELL, University of Oregon

Export Instability: The Latin American Case

DAVID H. POLLOCK AND NICASIO PERDOMI, Economic Commission for Latin America

Discussants: CHARLES P. KINDLEBERGER, Massachusetts Institute of Technology

GERTRUD LOVASY, International Monetary Fund

ROBERT Z. ALIBER, Committee for Economic Development

TAX REFORM

Chairman: WILLIAM J. FELLNER, Yale University*Papers:* The Bearing of the Problem on Capital Formation and the Use of Capital

DAN T. SMITH, Harvard University

Growth with Equity

RICHARD MUSGRAVE, Princeton University

Depreciation Problems

NORMAN TURE, National Bureau of Economic Research

Discussants: JOHN DUE, University of Illinois

EARL ROLPH, University of California, Berkeley

CHALLIS A. HALL, JR., Yale University

PROBLEMS OF REGIONAL INTEGRATION

Chairman: IRVING B. KRAVIS, University of Pennsylvania*Papers:* European Integration: Problems and Issues

BELA BALASSA, Yale University

Economic Integration and the Pattern of World Trade

ERIK THORBECKE, Iowa State University

European Economic Integration and the United States

LAWRENCE B. KRAUSE, The Brookings Institution

Discussants: RANDALL HINSEAW, Claremont College

PRICING AND RESOURCE ALLOCATION IN TRANSPORTATION AND PUBLIC UTILITIES

Chairman: MARTIN L. LINDAHL, Dartmouth College*Papers:* Pricing in Urban and Interurban Transport

WILLIAM S. VICKREY, Columbia University

The Influence of Transport Pricing and Regulation on Regional Location of Industry

LEON N. MOSES, Northwestern University

Practical Applications of Marginal Cost Pricing in the Public Utility Field

JAMES R. NELSON, Amherst College

Discussants: ELI W. CLEMENS, University of Maryland
 JULIAN S. DUNCAN, University of New Mexico
 ROY J. SAMPSON, University of Oregon

12:30 P.M. JOINT LUNCHEON WITH AMERICAN FINANCE ASSOCIATION

Chairman: EDWARD S. MASON, President, American Economic Association
Speaker: WILLIAM MCC. MARTIN, JR., Board of Governors, Federal Reserve System

2:30 P.M. ECONOMIC AND MARKETING ASPECTS OF THE NEW TRADE POLICY (Joint Session with American Marketing Association)

Chairman: WILLARD L. THORP, Amherst College

Papers: The New Trade Policy in Perspective

RAYMOND VERNON, Harvard University

Marketing Responses to the New Trade Policy

RONALD L. KRAMER, University of Pennsylvania

Discussants: JACK N. BEHRMAN, U.S. Department of Commerce

DON D. HUMPHREY, The Fletcher School of Law and Diplomacy

FRANK MEISSNER, School of World Business

HALE A. NEWCOMER, JR., Kent State University

FINANCIAL INSTITUTIONS AND MONETARY POLICY: A RE-EXAMINATION OF THEIR INTERRELATIONSHIP

Chairman: WARREN L. SMITH, University of Michigan

TJALLING C. KOOPMANS, Yale University

HERBERT A. SIMON, Carnegie Institute of Technology

5:00 P.M. BUSINESS MEETING

6:00 P.M. EXECUTIVE COMMITTEE DINNER MEETING

COLLEGE OF THE AIR'S "THE AMERICAN ECONOMY"

Beginning in late September, 1962, the American Economic Association joins with Learning Resources Institute, the Joint Council on Economic Education, and the National Task Force on Economic Education in sponsoring a college-credit course to be taught over a national television network. This course, which is but one major event in a program to increase economic literacy in the United States, is aimed in particular at high school teachers of social and business studies. But it is hoped that a wide audience of adults, college students, and perhaps advanced high school students will be attracted to watch the series regularly.

Members of the American Economic Association may have both a general interest in the content and execution of the course and a particular interest in viewing selected lessons taught by members of the profession. Key details and the outline of the course are as follows:

There will be 160 half-hour lessons. Four in each five will be devoted to economic content; the fifth lesson in each of the 32 weeks of the course will be on methods of introducing the economic content into the high school curriculum.

The course will be carried by most affiliates of the CBS Television network across the nation. Many of these affiliates will carry it at an early morning hour on each of the five weekdays in the weeks from September 24, 1962 through May 24, 1963. In communities where there are educational television stations, the course may be carried a second time each day at a later afternoon hour.

John R. Coleman, head of the department of economics at Carnegie Institute of Technology, is responsible for over-all content and for teaching more than half of the lessons and for coordinating the guest lectures. His associate for teacher education, who will conduct the 32 methods lessons for high school teachers is John H. Haefner of the State University of Iowa; and the associate for content planning is Kenneth O. Alexander of Michigan College of Mining and Technology.

Principal advisors to Coleman are the members of the National Task Force on Economic Education: G. L. Bach, of Carnegie Institute of Technology, chairman; Arno A. Bellack, Teachers College, Columbia University; Lester V. Chandler, Princeton University;

M. L. Frankel, Joint Council on Economic Education; Robert A. Gordon, University of California at Berkeley; Ben W. Lewis, Oberlin College; Paul A. Samuelson, Massachusetts Institute of Technology; Floyd A. Bond, University of Michigan.

Three hundred or more colleges and school systems across the country will give credit for the course, either in economics or in education. Each college sets its own rules for credit and administers its own examinations. Most will require that students seeking credit come to the campus at regular intervals for supplementary work. Regular assignments will be made throughout the course from a choice of four leading textbooks.

More detailed information on the course, the books, and the credit arrangements is available through Economic Education, P.O. Box 1601, Grand Central Station, New York 17, New York.

There follows an outline of the course which will be presented as College of the Air, "The American Economy."

May 23	159	The End is Just the Beginning
May 24	(160	Methods)

FELLOWSHIPS AND GRANTS

The Social Science Research Council's annual announcement describing fellowships and grants to be awarded in 1962-63 is now ready for distribution. It lists research training fellowships, faculty research fellowships, grants-in-aid of research, without major change and states that international conference travel grants will again be offered. Applications for some categories of awards are due not later than November 1, 1962. Inquiries should be addressed to the Social Science Research Council, Fellowships and Grants, 230 Park Ave., New York 17, N.Y.

The American Council of Learned Societies announces the continuation of aid to scholars in the form of fellowships, grants-in-aid and travel grants to international conferences. Address inquiries to Miss Marie J. Medina, American Council for Learned Societies, 345 East 46th Street, New York 17, N.Y.

Grants for area programs under joint ACLS-SSRC sponsorship will be offered to mature scholars for research in the social sciences and humanities on certain foreign areas. Grants for research on Africa South of the Sahara, on Latin America, and on the Near and Middle East (including North Africa) will be administered by the Social Science Research Council; while those for Asian Studies and for Slavic and East European Studies will be administered by the American Council of Learned Societies. Communications should be sent to the administering Councils at the addresses given in the two paragraphs above.

The National Science Foundation announces that the next closing date for receipt of basic research proposals in the social sciences is October 1, 1962. Proposals received prior to this date will be reviewed and notification of the Foundation's action will be made within four months. Proposals received after October 1, 1962 will be reviewed following the winter closing date of February 1, 1962. Inquiries should be addressed to the Division of Social Sciences, National Science Foundation, Washington 25, D.C.

Applications from younger faculty members and graduate students interested in continuing their study and research in the Soviet Union for all or part of the 1963-1964 academic year will be accepted by the Inter-University Committee on Travel Grants through November 16, 1962. Persons in all fields of study are encouraged to apply, provided that they can show reasonable professional and scholarly benefit to be derived from study and research in the Soviet Union. Applicants must be American citizens, and not more than approximately forty years of age. For further information as to other eligibility requirements and for application forms, write to Stephen Viederman, deputy chairman, Inter-University Committee on Travel Grants, Indiana University.

The Research Institute on Communist Affairs, at Columbia University, functioning under the Faculty of International Affairs, was established in October 1961. Its purpose is to study international communism and to examine the organization and activities of the Communist bloc. The Research Institute is designed to supplement the various regional studies conducted at Columbia University by the Russian Institute, the East Asian Institute, the Near and Middle East Institute, the Latin American Institute, the European Institute, the Program on East Central Europe, and the Program of African Studies. The Research Institute on Communist Affairs is devoted entirely to research and to the study of communism in its various international manifestation.

The Research Institute will make grants and/or its facilities available, either directly or jointly with the other Institutes to U.S. or foreign scholars who would like to work on a particular research project at the Research Institute, usually for approximately a year, as visiting research fellows, and to qualified government officials who might wish to spend a year free from official duties working within Columbia University on a research project pertaining to Communist affairs. For further inquiries, write to The Secretary, The Research Institute on Communist Affairs, Columbia University, New York 27, N.Y.

Two National Samples of the Population of the United States

In the June 1962 issue of the *Review*, announcement was made that the Bureau of the Census is planning to make available, on a cost basis, reels of magnetic tape or a set of

punchcards containing a one-in-a-thousand sample of the population of the United States, based on the returns of the 1960 Census. The Census Bureau has now completed its plans for this project. In addition to the one-in-a-thousand (.1 per cent) sample, a one-in-ten-thousand (.01 per cent) sample will also be prepared. The latter will be drawn from the .1 per cent sample set of punchcards and will contain the same population and housing information. Among the many subjects covered are personal and family income, employment status, occupation, industry, geographic mobility, education, automobiles, and housing facilities and equipment.

A detailed description of the content of the tape and punchcards on which the samples will be available and information as to cost can be obtained by writing to the Director, Bureau of the Census, Washington 25, D.C.

Announcements

The annual meeting of the Conference on the History of Western America will be held at the Albany Hotel, Denver, Colorado, October 11-13, 1962. R. G. Athearn, of the University of Colorado, is the program chairman. Papers will represent disciplines in social sciences, the humanities and the sciences.

The Industrial College of the Armed Forces extends an invitation to qualified civilians in business, industry and the professions to enroll in its graduate-level correspondence course, entitled "The Economics of National Security." Operating under the direction of the Joint Chiefs of Staff, the Industrial College conducts courses of study in the economic and industrial aspects of national security in the context of both national and world affairs, giving due consideration to military, logistical, administrative, scientific, technological, political, and social factors affecting national security.

Deaths

Lee Galloway, Winter Park, Florida, January 31, 1962.

Orville J. Hall, Fayetteville, Arkansas, September 27, 1961.

George S. Mitchell, Glencoe, Scotland, April 12, 1962.

Charles E. Persons, Mount Vernon, Iowa.

Paul Studenski, November 2, 1961.

Retirements

Benjamin H. Beckhart, Columbia University.

Raymond T. Bye, Wharton School, University of Pennsylvania.

Samuel M. Derrick, University of South Carolina School of Business Administration.

Herbert B. Dorau, New York University School of Commerce.

H. LaRue Frain, Wharton School, University of Pennsylvania.

John H. Frederick, University of Maryland.

Milton S. Heath, University of North Carolina School of Business Administration.

Paul V. Horn, New York University School of Commerce.

Lucy W. Killough, Wellesley College.

Gertrude P. Meek, Florida State University.

Clyde W. Phelps, University of Southern California.

William E. Warrington, Wharton School, University of Pennsylvania.

Elmer Wood, as emeritus professor, University of Missouri.

Visiting Foreign Scholars

George C. Archibald, The London School of Economics; acting associate professor of economics, University of California, Berkeley, 1962-63.

Antonius P. Barten, Econometric Institute, Netherlands School of Economics, Rotterdam; visiting lecturer in economics, University of California, Berkeley, 1962-63.

Duncan Black, University College of North Wales: visiting scholar at Thomas Jefferson Center for Studies in Political Economy, University of Virginia, fall 1962; visiting professor of economics and political science, University of Rochester, spring 1963.

Burgess D. Cameron, Australian National University: visiting professor, department of economics, University of California, Berkeley, fall 1962.

Thomas R. DeGregori, University of Khartoum, Sudan: visiting lecturer in economics, University of Texas.

John H. Habakkuk, Oxford University: visiting Ford research professor, Department of Economics, University of California, Berkeley, 1962-63.

Colin D. Harbury, University of Birmingham, England: visiting lecturer in economics, San Diego State College, 1962-63.

John Lübbert, Kiel University, Germany: visiting associate professor, department of economics, University of Illinois.

Paul P. Streeten, Balliol College, Oxford; fellow, Center for Advanced Studies, Wesleyan University.

Tore S. Thonstad, University of Oslo: visiting professor of economics, University of Minnesota.

John Wise, University of Birmingham, England: visiting professor of economics, Stanford University.

John Wiseman, The London School of Economics: visiting professor of economics, University of California, Berkeley, 1962-63.

Promotions

Arthur T. Andersen: assistant professor of economics, Boston University.

Leo I. Bakony: associate professor of economics, Southern Methodist University.

Joseph S. Berliner: professor of economics, Syracuse University.

James H. Blackman: professor, School of Business Administration, University of North Carolina.

George F. Break: professor of economics, University of California, Berkeley.

Phillip D. Cagan: professor of economics, Brown University.

Vincent Cangelosi: associate professor of business administration, University of Arkansas College of Business Administration.

S. H. Chou: professor of economics, University of Pittsburgh.

Jacob Cohen: professor of economics, Bowling Green State University.

Joseph D. Coppock: research professor of economics, Earlham College.

J. M. Culbertson: professor of economics and commerce, University of Wisconsin.

Lance Davis: professor of economics, Purdue University.

Richard M. Davis: professor of economics, University of Oregon.

Ralph L. Day: associate professor, department of marketing, University of Texas College of Business Administration.

Milton T. Edelman: professor of economics, Southern Illinois University.

Sidney P. Feldman: associate professor of business administration, University of Kansas School of Business.

C. E. Ferguson: professor, department of economics and business administration, Duke University.

William H. Fink: professor of economics, University of Arizona.

Joe S. Floyd, Jr.: professor, School of Business Administration, University of North Carolina.

Leonard J. Garrett: assistant professor, geography and industry department, Wharton School, University of Pennsylvania.

- Gregory Grossman: professor of economics, University of California, Berkeley.
- James M. Henderson: professor of economics, University of Minnesota.
- Charles Howe: associate professor of economics, Purdue University.
- Dell B. Johannesen: associate professor, School of Business Administration, University of North Carolina.
- Paul E. Junk: associate professor of economics, University of Missouri.
- Arcadius Kahan: associate professor of economics, University of Chicago.
- Gerald J. Karaska: assistant professor, department of geography and industry, Wharton School, University of Pennsylvania.
- Thomas F. Keller: associate professor, department of economics and business administration, Duke University.
- Sidney Klein: associate professor of economics, Rutgers—the State University.
- A. J. Kondonassis: associate professor of economics, University of Oklahoma.
- Juanita M. Kreps: associate professor, department of economics and business administration, Duke University.
- William L. Larger: associate professor of marketing, University of Louisville School of Business.
- Henry A. Latané: professor, University of North Carolina School of Business Administration.
- Stewart M. Lee: professor of economics, Geneva College.
- Herbert S. Levine: associate professor of economics, Wharton School, University of Pennsylvania.
- Robert W. Lewis: associate professor of business administration, University of Kansas School of Business.
- H. H. Liebhafsky: professor of economics, University of Texas.
- Edward O. Lutz: associate professor, Brooklyn College.
- Edward Marcus: professor, Brooklyn College.
- Shelley M. Mark: professor of economics, University of Hawaii.
- Campbell R. McConnell: professor of economics, University of Nebraska.
- Leahmae McCoy: associate professor of economics, University of Arizona.
- Jacob Mincer: professor of economics, Columbia University.
- Jerry Miner: associate professor, department of economics, Syracuse University.
- Vernon G. Morrison: associate professor, department of economics, Southern Illinois University.
- Leon Moses: professor and director of research, Transportation Center, Northwestern University.
- Walter C. Neale: associate professor of economics, University of Texas.
- Erwin E. Nemmers: professor of business administration, Northwestern University Graduate School of Business Administration.
- Archie J. Nichols: professor, Butler University.
- Wallace C. Peterson: professor of economics, University of Nebraska.
- Richard W. Poole: associate professor of economics, Oklahoma State University.
- W. F. Putnam: assistant professor, University of South Carolina School of Business Administration.
- Charles A. Ray: associate professor of management, New York University School of Commerce, Accounts, and Finance.
- Marion Ross: associate professor of economics, Mills College.
- Richard L. Rowan: assistant professor, department of geography and industry, Wharton School, University of Pennsylvania.

George G. Sause: professor of economics, Lafayette College.

Eric Schenker: associate professor of economics, University of Wisconsin, Milwaukee.

Jacob Schmookler: professor of economics, University of Minnesota.

Steven J. Shaw: professor, University of South Carolina School of Business Administration.

John A. Shubin, professor of economics, New York University School of Commerce.

Milton Silver: assistant professor, department of geography and industry, Wharton School, University of Pennsylvania.

Norman J. Simler: associate professor of economics, University of Minnesota.

Sidney I. Simon: professor of economics, Rutgers—the State University.

Burnard Sord: professor of management and associate dean of the College of Business Administration, University of Texas.

Charles E. Staley: associate professor of economics, University of Kansas.

Jerome L. Stein: professor of economics, Brown University.

Benjamin H. Stevens: associate professor of regional science, Wharton School, University of Pennsylvania.

James A. Storer: professor of economics, Bowdoin College.

Gerald E. Thompson: associate professor of economics, University of Nebraska.

Rollie Tillman: assistant professor, University of North Carolina School of Business Administration.

Lewis E. Wagner: professor, department of economics, University of Illinois.

Marshall D. Wattles: professor of economics, University of Oregon.

Francis O. Woodard: assistant professor of economics, University of Nebraska.

Rolf S. Wubbels: professor of finance, New York University School of Commerce.

Administrative Appointments

Ralph L. Andreano: associate professor and chairman, department of economics, Earlham College.

J. F. Bennett: assistant treasurer, Standard Oil Company (New Jersey).

W. Donald Bowles: associate professor and chairman, department of economics, American University.

Louis F. Buckley: regional administrator, Bureau of Employment Security, U. S. Department of Labor, New York City.

J. Whitney Bunting: dean of the College of Business Administration, University of Georgia.

Allan M. Cartter: vice president, American Council on Education.

Paul G. Clark: acting chairman, department of economics, Williams College.

Sidney Davidson: director and Arthur Young professor of accounting, Institute of Professional Accountancy, Graduate School of Business, University of Chicago.

Walter D. Fackler: associate dean, Graduate School of Business, University of Chicago.

Claude S. George, Jr.: associate dean, School of Business Administration, University of North Carolina.

Paul C. Goetz: acting dean, School of Business Administration, St. Mary's University.

Henry Grayson: professor and chairman of the department of business economics, University of Hawaii.

Burton C. Hallowell: vice president, Wesleyan University.

Edgar M. Hoover, director, Center for Regional Economic Studies, University of Pittsburgh.

Robert H. Johnson: chief of mission, The Brookings Institution Economic Specialists

Group in Saigon for another two-year tour, having resigned from the University of Iowa.

Jacob J. Kaplan: director, International Development Organizations Staff, Agency for International Development.

Burton H. Klein: head, economics department, RAND Corporation.

Irving B. Kravis: chairman, economics department, Wharton School, University of Pennsylvania.

William H. Meckling: head, economics division, Operations Evaluation Group, Arlington, Virginia.

Wiley S. Mitchell: acting dean, University of Kansas School of Business.

Aurelius Morgner: chairman, department of economics, University of Southern California.

Ronald R. Olsen: acting chairman, department of economics, University of Kansas.

Joseph A. Pechman: director of economic studies, Brookings Institution.

John H. Prime: dean, School of Commerce, Accounts, and Finance, New York University.

Edwin P. Reubens: acting chairman, department of economics, The City College of New York.

Warren C. Scoville: director, Bordeaux Center, University of California, Bordeaux, France.

James R. Surface: vice-chancellor and dean of faculties, University of Kansas.

W. Bayard Taylor: dean, Claremont Graduate School, Claremont Men's College.

Carey C. Thompson: chairman, department of economics, University of Texas.

W. Allen Wallis, University of Chicago: president, University of Rochester.

Marshall D. Wattles: acting dean, College of Liberal Arts, University of Oregon.

Appointments

Robert Adams: instructor in economics, University of Michigan.

Irma Adelman: associate professor of political economy, Johns Hopkins University.

Sydney N. Afriat: associate professor of economics, Rice University.

Dennis J. Aigner, University of California: assistant professor of economics, University of Illinois.

Isabel B. Anderson: instructor in economics, department of economics and political science, University of Saskatchewan.

Leslie P. Anderson, University of Arizona: assistant professor of economics and management, Purdue University.

Richard E. Attiye: assistant professor of economics, Stanford University.

G. Paul Balabanis, University of California, Berkeley: assistant professor, department of economics, San Diego State College.

Richard Baltz: assistant professor of economics, College of Business Administration, University of Arkansas.

Morton S. Baratz: visiting associate professor of economics, Wharton School, University of Pennsylvania.

Edward E. Barr, Freeport Sulphur Co.: long-range planning analyst, Sun Chemical Corporation.

William B. Barrett: assistant professor, department of accounting, University of Texas College of Business Administration.

Winston C. Beard, University of Arkansas: assistant professor, department of finance, College of Business Administration, University of Texas.

Morris Beck, Rutgers—the State University: on special project at the National Bureau of Economic Research.

Hrack Bedrosian: instructor in management, New York University School of Commerce.

Maurice Benowitz: visiting lecturer in economics, Hofstra College.

Dean F. Berry: assistant professor of geography and industry, Wharton School, University of Pennsylvania.

William K. Bethauser: instructor in management, New York University School of Commerce.

Robert C. Bingham, University of Nebraska: Kent State University.

Howard R. Bloch: assistant professor of economics, Butler University.

George B. Breckenridge: instructor in political economy, department of economics and political science, University of Saskatchewan.

Albert Buckberg, Iowa State University: U. S. Bureau of the Budget.

Dean B. Cameron: visiting professor of economics, Wharton School, University of Pennsylvania.

David J. Cantor: instructor, department of economics, Boston University.

William M. Capron, Stanford University: Council of Economic Advisers, Washington, D.C.

John A. Carlson, Cornell University: assistant professor of economics, Purdue University.

Joseph Chao: assistant professor of economics, Denison University.

Kang Chao: assistant professor of economics, University of Michigan.

Frank C. Child, Michigan State University: associate professor of economics, University of California, Davis.

George A. Christy: assistant professor of finance, University of Oregon.

Herman Clurman: associate professor of accounting, New York University School of Commerce.

Robert T. Collins: professor of economics, School of Business Administration, University of South Carolina.

Maynard S. Comiez, Federal Reserve System: fiscal economist, Bureau of the Budget.

R. Gene Conatser: instructor in economics, Tarleton State College.

Leonard J. Corti: vice president, Allied Research Associates, Inc., Boston, Massachusetts.

Robert L. Crouch, University of California, Los Angeles, and The London School of Economics: lecturer, Northwestern University.

John H. Cover, retired from the University of Maryland: economic planning consultant to Syria under the United Nations.

Paul A. Crowe, Tulane University: assistant professor of economics, College of Business Administration, University of Georgia.

Frederick R. Dahl, Federal Reserve System: Balance of Payments Advisor to the Central Bank of Nigeria, with the Agency for International Development.

Tom E. Davis: associate professor, Cornell University.

George Delehanty, Massachusetts Institute of Technology: assistant professor, Northwestern University.

Paul Demeny: assistant professor of economics, Princeton University.

Edward F. Denison, Committee for Economic Development: senior staff, Brookings Institution.

Herbert S. Dennenberg: assistant professor of insurance, Wharton School, University of Pennsylvania.

William G. Dewald: assistant professor of economics, University of Chicago.

Pedro P. Diaz Maestre: assistant professor of accounting, College of Business Administration, University of Georgia.

Frank G. Dickinson, National Bureau of Economic Research: professor of economics, Northern Illinois University.

Joel B. Dirlam: professor of economics, Michigan State University.

Giuseppe M. Ferrero diRoccafererra: associate professor, geography and industry department, Wharton School, University of Pennsylvania.

Manoranjan Dutta: visiting assistant professor of economics, Rutgers—The State University.

Henry Einhorn: assistant professor of economics, Michigan State University.

Walter L. Eisenberg: associate professor of economics, Hunter College.

Houston G. Elan: instructor in marketing, New York University School of Commerce.

Roger K. Eyvindson: research associate, department of economics, Iowa State University.

David Fand, Southern Methodist University: appointment at the University of Buffalo.

Attiat Farag: assistant professor of economics, Southern Methodist University.

Helen Farr, Bryn Mawr College: instructor, Mount Holyoke College.

Alan E. Fechter: assistant professor of economics, research staff, Center for Regional Economic Studies, University of Pittsburgh.

John R. Felton: assistant professor of economics, University of Nebraska.

Albert Fishlow, University of California: on the staff of the National Bureau of Economic Research, beginning February 1963.

Miles Fleming: lecturer in economics, Wharton School, University of Pennsylvania.

John E. Floyd, University of Chicago: assistant professor of economics, University of Washington.

Herman Freudenberger: associate professor of economics, Tulane University.

Robert E. Gallman: associate professor of economics, School of Business Administration, University of North Carolina.

Francis W. Gathof, Jr.: assistant professor, department of economics, Beloit University.

Herbert Geyer, Southern Methodist University: associate professor of economics, Tulane University.

Harry J. Gilman: lecturer in economics, Rutgers—the State University.

Alex S. Gonzales, University of Oregon: assistant professor of business administration and economics, The College of Idaho.

Craufurd D. Goodwin, York University, Toronto, Canada: assistant professor of economics, Duke University.

Tom E. Gossett: assistant professor, department of accounting, College of Business Administration, University of Texas.

David G. Greene: lecturer in economics, Rutgers—the State University.

Mark R. Greene: professor of insurance, University of Oregon.

Melvin L. Greenhut: professor, department of economics, Florida State University.

Joan Greenwood, University of California: instructor in economics, Wellesley College.

Charles H. Griffin: visiting professor, department of accounting, College of Business Administration, University of Texas.

Bertram M. Gross, Maxwell School, Syracuse University: Leatherbee Lecturer on management, Harvard Graduate School of Business Administration, fall term 1962.

Herbert G. Grubel: acting assistant professor of economics, Stanford University.

John D. Guilfoil: instructor in economics, New York University School of Commerce.

Jack M. Guttentag: associate professor of finance, Wharton School, University of Pennsylvania.

Harry P. Guenther: visiting associate professor of finance, University of Minnesota.

Josef Hadar: assistant professor of economics, Michigan State University.

Geoffrey B. Hainsworth, Harvard University: Research School of Pacific Studies, Australian National University.

Alvin H. Hansen, Harvard University: distinguished visiting professor, Michigan State University.

Clyde E. Harris, University of Arkansas: assistant professor of economics, College of Business Administration, University of Georgia.

Dale S. Harwood, Jr.: associate professor of accounting, University of Oregon.

Leland Hazard: visiting professor of geography and industry, Wharton School, University of Pennsylvania.

Bernard P. Herber: assistant professor of economics, University of Arizona.

Alan W. Heston: assistant professor of economics, Wharton School, University of Pennsylvania.

George W. Hilton: lecturer in economics, University of California, Los Angeles.

Merle Hostetler, Federal Reserve Bank of Cleveland: vice president and economist, Union Commerce Bank, Cleveland, Ohio.

Norman S. Hubbard, Yale University: instructor in economics, Hofstra College.

John A. Hynes, University of Chicago: assistant professor of economics, University of Washington.

Leland H. Jenks: visiting professor of economic history, Tulane University.

Robert S. Johnson: lecturer, James Wilson department of economics, University of Virginia.

Thomas M. Johnson: assistant professor of economics, University of Missouri.

Walter L. Johnson: instructor, department of economics and business administration, Duke University.

Lawrence D. Jones, Jr., Harvard University: assistant professor of economics, Wesleyan University.

Norman Jones: research economist, The RAND Corporation.

Charles J. Jorgensen: professor of economics, University of Washington.

Joseph A. Klapowski: instructor in accounting, New York University School of Commerce.

Herbert E. Klarman: lecturer in political economy and associate professor of public health administration, Johns Hopkins University.

K. C. Kogiku: assistant professor of economics, University of California, Riverside.

James C. LaForce, Jr.: visiting assistant professor of economics, University of California, Los Angeles.

Kelvin J. Lancaster: professor of political economy, Johns Hopkins University.

Robert Landolt, University of Texas: professor of economics and business, Morris Harvey College, Charleston, West Virginia.

Robert Lawrence: instructor in economics, University of Michigan.

J. William Leasure, Princeton University: assistant professor, department of economics, San Diego State College.

Stanley Lebergott, U. S. Bureau of the Budget: professor, Wesleyan University.

John D. Lehman, Denison University: assistant professor of economics, Wells College.

Eugene M. Lerner: visiting lecturer in economics, Hofstra College.

Charles L. Leven, University of Pennsylvania: associate professor of economics, research associate, Center for Regional Economic Studies, University of Pittsburgh.

Bertram F. Levin: visiting associate professor, James Wilson department of economics, University of Virginia.

E. E. Liebhafsky, Texas A. and M. College: visiting professor, North Carolina State College.

- Nissan Liviatan: lecturer in economics, Wharton School, University of Pennsylvania.
- Charles R. Lockyer, now completing an assignment with Public Administration Service in Thailand: research associate, Bureau of Business Research, University of Kentucky.
- Melvin Lurie: visiting associate professor of economics, Wesleyan University.
- Matityahu Marcus: lecturer in economics, Rutgers—the State University.
- F. Ray Marshall: professor of economics, University of Texas.
- Alvin L. Marty: visiting associate professor of economics, University of Chicago.
- Leo V. Mayer: research associate, department of economics, Iowa State University (Ames).
- Jackson M. McClain, University of Alabama: research associate, Bureau of Business Research, University of Kentucky.
- David Meiselman: position with the U. S. Treasury.
- Jack Melitz: assistant professor of economics, Rice University.
- Ronald Miller: assistant professor of regional science, Wharton School, University of Pennsylvania.
- William L. Miller, Auburn University: professor of economics, College of Business Administration, University of Georgia.
- John B. Miner: professor of management, University of Oregon.
- Robert A. Minick, University of Texas: assistant professor of economics, Fresno State College, California.
- Franco Modigliani, Northwestern University: professor, School of Industrial Management, Massachusetts Institute of Technology.
- Dannie J. Moffie: associate professor of business administration, School of Business Administration, University of North Carolina.
- Russell L. Moran, Cornell University: assistant professor, department of economics, University of Illinois.
- M. G. Mueller: assistant professor of economics, University of California, Los Angeles.
- Robert G. Murdick: professor of management, School of Business, University of Louisville.
- Edward J. Nell, Nuffield College, Oxford: assistant professor of economics, Wesleyan University.
- Hugh O. Nourse: assistant professor of economics, Washington University.
- John C. O'Brien: assistant professor of economics, department of economics and political science, University of Saskatchewan.
- Walter Y. Oi, University of Chicago: visiting associate professor of economics, University of Washington.
- William Pendleton: associate professor of economics and research associate, Center for Regional Economic Studies, University of Pittsburgh.
- Mark Perlman, Johns Hopkins University: professor of economics, University of Pittsburgh.
- Keith Phillips: assistant professor, economics department, Syracuse University.
- James Pickett: visiting assistant professor of economics, department of economics and political science, University of Saskatchewan.
- Lon Polk: instructor in economics, University of Michigan.
- Joel Popkin, University of Pennsylvania: lecturer, Northwestern University.
- James Price: assistant professor, economics department, Syracuse University.
- Frederic Pryor: assistant professor of economics, University of Michigan.
- John T. Rader: assistant professor of economics, University of Missouri.
- Helen Raffel: assistant professor of economics, Wharton School, University of Pennsylvania.

J. A. Ramirez, First Western Bank: Lockheed Missiles and Space Company.

J. C. Rao: lecturer in finance, Wharton School, University of Pennsylvania.

Thomas A. Reiner: lecturer in regional science, Wharton School, University of Pennsylvania.

Edward F. Renshaw: assistant professor, School of Business Administration, University of North Carolina.

Timothy Rice: assistant professor, economics department, Syracuse University.

Bruce W. Roberson: instructor, department of accounting, College of Business Administration, University of Texas.

Robert Robertson, University of Cincinnati: assistant professor of economics, Mount Holyoke College.

David Robinson: associate professor of business administration, College of Business Administration, University of Arkansas.

Jack L. Robinson, Ohio State University: assistant professor of economics, department of economics, University of Oklahoma.

Peter Rosko: lecturer in finance, University of Minnesota.

Simon Rottenberg: professor of industrial relations, University of Buffalo.

G. Gareld Rusk, University of Texas: assistant professor of economics, Sam Houston State College.

Seymour Sacks: associate professor, economics department, Syracuse University.

Arnold E. Saffer: assistant professor of economics, Rice University.

Roy J. Sampson: associate professor of transportation, University of Oregon.

John M. Scheidell, Kalamazoo College: associate professor of economics, College of Business Administration, University of Georgia.

Bernard Schwartz: visiting professor, Michigan State University, spring term 1963.

Robert C. Shackelford, University of California: instructor, department of economics, University of Illinois.

Irwin A. Shapiro, Northwestern University: assistant professor, department of marketing, College of Business Administration, University of Texas.

Ronald A. Shearer, University of Michigan: Toronto Royal Commission on Banking and Finance.

Howard J. Sherman, Wayne State University: assistant professor of economics, California Institute of Technology.

Robert A. Sigafos, Stanford Research Institute: senior research fellow in economics, California Institute of Technology.

Hugo M. Skala: professor of economics, Fairleigh Dickinson University, Rutherford Campus.

Norman R. Smith: assistant professor of marketing, University of Oregon.

Robert E. Smith, University of Utah: lecturer in economics, University of Oregon.

Wendell R. Smith: professor of marketing, Wharton School, University of Pennsylvania.

Eugene Smolensky: visiting assistant professor of economics, Wharton School, University of Pennsylvania.

Allen R. Solem: professor of management, University of Minnesota.

Edward Stevens: assistant professor, economics department, Syracuse University.

Ian Stewart: instructor, Dartmouth College.

Joann P. Stewart: instructor, economics department, Boston University.

Milton D. Stewart, University of Texas: assistant professor, University of Maryland Extension, Japan.

Bernt P. Stigum: assistant professor, department of economics, Cornell University.

Marcia Stigum, Massachusetts Institute of Technology: instructor in economics, Wellesley College.

Boris C. Swerling, Food Research Institute, Stanford University: Division of International Finance, Board of Governors of the Federal Reserve System.

Donald G. Tailby, Lehigh University: assistant professor of economics, College of Business Administration, University of Georgia.

Michael B. Teitz: lecturer in regional science, Wharton School, University of Pennsylvania.

Earl A. Thompson: assistant professor of economics, Stanford University.

Paul Thompson: instructor in economics, Michigan State University.

Charles M. Tiebout, University of California, Los Angeles: professor of economics, University of Washington.

Jack Topiol: instructor in economics, Rutgers—The State University.

Clarence O. Tuck: instructor in accounting, New York University School of Commerce, Accounts, and Finance.

Leo J. Turner: instructor in marketing, New York University School of Commerce.

Dale Tussing: lecturer, economics department, Syracuse University.

Hylke Van De Wetering: research associate, department of economics, Iowa State University.

Peter Vandome: lecturer in statistics, Wharton School, University of Pennsylvania.

Jack R. Vernon: assistant professor of economics, Michigan State University.

Caron R. Waits, University of Texas: assistant professor of economics, Texas Christian University.

Kornelis J. Walraven, University of Arkansas: assistant professor, department of finance, College of Business Administration, University of Texas.

James E. Walter: professor of finance, Wharton School, University of Pennsylvania.

Ralph J. Watkins: vice president and member of Board of Directors, Surveys & Research Corporation; is continuing to supervise the Brookings Institution Economic Specialists Group in Saigon.

Donald Q. Webb: assistant professor of economics, Centre College.

Harrison Wehner: instructor in economics, University of Michigan.

Jerry Wells: instructor in economics, University of Michigan.

William Wendt: assistant professor of economics, American University.

Katherine M. West: assistant professor, Brooklyn College.

W. Terry Wilford, Southern Methodist University: assistant professor of economics, University of Georgia.

Thomas H. Williams: assistant professor, department of accounting, College of Business Administration, University of Texas.

Mervyn W. Wingfield: associate professor of accounting, School of Business Administration, University of South Carolina.

Robert I. Winter: instructor in economics, New York University School of Commerce.

David McC. Wright, McGill University: professor of economics, College of Business Administration, University of Georgia.

Leaves for Special Appointments

Kenneth G. Ainsworth, Allegheny College: economist, U. S. House of Representatives Subcommittee on State Taxation of Interstate Commerce, 1961-62 and 1962-63.

Robert J. Alexander, Rutgers—The State University: visiting professor, Columbia University, 1962-63.

Willard Allan, Standard Oil Company (Ohio): Head of the Department of Economics and Statistics, The Operating Companies (Consortium), Teheran, Iran, for two years.

Leslie P. Anderson, Purdue University: economist-statistician for a special study of securities markets by the Securities and Exchange Commission.

Lowell D. Ashby, University of North Carolina: to work on a research program with the U. S. Department of Commerce.

Marto A. Ballesteros, University of Washington: senior economist, Tax and Fiscal Policy Unit of the Pan American Union sponsored by the Organization of American States, 1962-63.

Robert L. Basmann, University of Chicago: visiting professor of economics, University of Minnesota, spring quarter, 1962-63.

Martin J. Beckmann, Brown University: University of Bonn, first semester 1962-63.

James C. D. Blaine, University of North Carolina: transportation consultant to the National Council for Applied Economic Research, New Delhi, India, 1962-63.

Louis K. Brandt, University of Mississippi: visiting professor, College of Business Administration, University of Texas.

Martin Bronfenbrenner, University of Minnesota: visiting professor of economics, Carnegie Institute of Technology, 1962-63.

Denzel C. Cline, Michigan State University: research and lecturer, University of Ankara, Turkey, 1962-63.

Sanford Cohen, Butler University: visiting professor, Institute of Industrial Relations, University of Illinois, 1962-63.

John M. Culbertson, University of Wisconsin: visiting professor of economics, University of California, Berkeley, 1962-63.

Stephen Enke, Duke University: assistant to the president, Institute for Defense Analysis, Washington, D.C., 1962-63.

Lowell E. Gallaway, San Fernando Valley State College: visiting associate professor, University of Minnesota, 1962-63.

William B. Gates, Jr., Williams College: economist, Surveys and Research Corporation, Djakarta, Indonesia.

Peter Gregory, University of Minnesota: staff member of a program in industrial relations and labor economics at the University of Chile, Santiago, sponsored by AID and administered by Cornell University, 1962-63.

Richard B. Heflebower, Northwestern University: visiting professor, Harvard University, 1962-63.

John P. Henderson, Michigan State University: University of Nigeria, Nsukka, for two years.

William R. Hughes, Wesleyan University: economist with the Federal Power Commission, 1962-63.

John M. Hunter, Michigan State University: advisor to the Institute of Economic Research, University of Cordoba, Argentina, 1962-63.

John H. Kareken, University of Minnesota: consultant, U. S. Treasury Department, 1962-63.

Richard H. Leftwich, Oklahoma State University: visiting professor of economics, University of Chicago, to serve as consultant to the department of economics, The Catholic University of Chile, Santiago.

Daniel Marx, Jr., Dartmouth College: senior economist, Stanford Research Institute, 1962-63.

E. Scott Maynes, University of Minnesota: consultant, Bureau of the Census, Washington, D.C., 1962-63.

Paul Medow, Rutgers—The State University: Ford Foundation Faculty Research Fellowship, economic development and administration program, 1962-63.

John A. Menge, Dartmouth College: National Science Foundation Fellow, Nuffield College, Oxford University, 1962-63.

J. W. Milliman, Indiana University: temporary assignment with Resources for the Future, Inc.

Judson Neff, University of Texas: to teach industrial management as a member of the economics faculty for the University of Wisconsin-Ford Foundation Project at Gadjah Mada University, Jogjakarta, Indonesia.

Richard L. Pfister, Dartmouth College: consultant, Office of International Tax Affairs, U. S. Treasury Department.

Howard S. Piquet, Legislative Reference Service, Library of Congress: Ford distinguished professor, New York University, fall semester 1962-63.

Vernon W. Ruttan, Purdue University: economist, Council of Economic Advisers, Washington, D.C.

Sayre P. Schatz, Hofstra College: senior research fellow, Nigerian Institute for Social and Economic Research, 1962-63.

Norman J. Simler, University of Minnesota: senior economist, Council of Economic Advisers, Washington, D.C., 1962-63.

Larry A. Sjaastad, University of Minnesota: department of economics, University of Chicago to establish an Economic Research Center at the National University of Cuyo, Mendoza, Argentina, project sponsored by I.C.A., 1962-63.

Jack Steele, University of Kansas: to teach at IMEDE, Lausanne, Switzerland, for one year.

Milton C. Taylor, Michigan State University: advisor to Pan American Union, Washington, D.C., 1962-63.

George J. Viksnins, Hood College: Board of Governors of the Federal Reserve System, summer 1962; teaching fellow, Georgetown University, 1962-63.

Fred Westfield, Northwestern University: visiting professor, Vanderbilt University, 1962-63.

G. G. Williamson, Jr., University of South Carolina: lecturer at Johns Hopkins University Bologna Center at Bologna, Italy.

Resignations

Roy A. Church, University of Washington.

Kenneth E. Cook, Bureau of Business Research, University of Kentucky.

John D. DeForest, Denison University.

Harry Franklin, Georgetown University.

Jesse Friedman, Georgetown University.

Louis Hamill, University of Oregon.

Harald B. Malmgren, Cornell University.

Thomas Mayer, Michigan State University.

Morton F. Moss, University of Oregon.

William N. Parker, University of North Carolina.

Giulio Pontecorvo, University of Washington.

Melvin Rothbaum, University of California, Los Angeles.

Edward C. Simmons, Duke University.

David E. Snyder, Wharton School, University of Pennsylvania.

Donald F. Swanson, University of South Carolina.

Koji Taira, University of Washington.

Scott D. Walton, University of Oregon.

George Wythe, Georgetown University.

FIFTY-NINTH LIST OF DOCTORAL DISSERTATIONS IN POLITICAL ECONOMY IN AMERICAN UNIVERSITIES AND COLLEGES

The present list specifies doctoral degrees conferred during the academic year terminating June 1962, and theses undertaken in the same period.

General Economics; Methodology

Degrees Conferred

ROBERT T. AVERITT, Ph.D. Texas 1961. The developmental power of institutionalist thinking.

Price and Allocation Theory; Income and Employment Theory; History of Economic Thought

Degrees Conferred

CLOPPER ALMON, JR., Ph.D. Harvard 1962. Consistent forecasting in a dynamic general equilibrium system.

STANLEY BOBER, Ph.D. New York 1962. The cyclical behavior of retail inventories.

JOHN A. CARLSON, Ph.D. Johns Hopkins 1961. Investment decisions in the face of technological change.

CHARLES E. CARPENTER, Ph.D. Colorado 1961. Geographic variations in the consumer price index.

WERNER L. CHILTON, Ph.D. Columbia 1962. Direct business investment and the choice of technology.

MARCIA D. DAVIDSON, Ph.D. Duke 1962. Three Spanish economists of the enlightenment: Campomanes, Jovellanos, Florez Estrada.

RICHARD H. DAY, Ph.D. Harvard 1961. Recursive programming and production response.

EDWARD GREENBERG, Ph.D. Wisconsin 1961. Business investment in new plant and equipment: an empirical study.

MARSHALL M. HALL, Ph.D. Wisconsin 1961. Investment in research and development: a statistical study.

ALBERT A. HIRSCH, Ph.D. Duke 1960. A taxonomic study of certain models of economic growth.

A. C. HOUSTON, Ph.D. Pennsylvania State 1962. The Stockholm School—a study of the evolution of economic theory.

DAVID SHIH-LI HUANG, Ph.D. Washington 1961. The demand for automobiles in 1956 and 1957—a cross-section analysis.

ESTELLE D. JAMES, Ph.D. Mass. Inst. Technology 1961. Reconsideration of the theoretical criteria for investment planning.

LOUIS J. JUNKER, Ph.D. Wisconsin 1962. The social and economic thought of Clarence Edwin Ayres.

MORDECAI, KURZ, Ph.D. 1962. Patterns of growth and valuation in a two sector model.

JOHN E. LA TOURETTE, Ph.D. Rutgers 1962. Innovation and technological change in growth models—a critical study.

CHARLES W. MEYER, Ph.D. Johns Hopkins 1961. The cost function for local telephone service: increasing or decreasing?

- THOMAS S. MORI, Ph.D. Catholic 1962. The theory of supply and demand in the English classical school from Smith to Cairnes.
- ROY E. MURPHY, Ph.D. Stanford 1962. Adaptive processes in economic systems.
- BERNARD NEWTON, Ph.D. Columbia 1962. The economics of Francis Amasa Walker: American economics in transition.
- GEORGE L. PERRY, Ph.D. Mass. Inst. Technology 1961. Aggregate wage determination and the problem of inflation.
- BLAISE F. REINHART, Ph.D. Catholic 1962. The life of Richard Jones and his contribution to economic methodology and theory.
- KRISHNA P. SHARMA, Ph.D. Oregon 1962. A study in the theory of economic growth and income distribution.
- T. N. SRINIVASAN, Ph.D. Yale 1962. Investment criteria and choice of techniques of production.
- BERNT P. STIGUM, Ph.D. Harvard 1962. Statistical decision theory for discrete stochastic processes with applications to dynamic economic theory.
- EARL A. THOMPSON, Ph.D. Harvard 1962. Technical change, its measurement and integration into the theory of the firm with special application to the explanation of the building cycle.
- MARK L. WEHLE, Ph.D. Columbia 1962. The interest elasticity of the ratio of fixed investment to national income as estimated from engineering payout studies.
- GILBERT R. WHITAKER, JR., Ph.D. Wisconsin 1961. Decision unit model of the production and inventory decisions.
- JAMES R. WILLIAMS, Ph.D. Minnesota 1962. An estimation of the parameters in the regression of observed consumption on observed income when both are assumed to include random variables.
- PAN A. YOTOPOULOS, Ph.D. California (Los Angeles) 1962. Disguised unemployment and elastic supplies of labor: the theory and an empirical test for Greece.

Theses in Preparation

- HENRY J. AARON, B.A. California (Los Angeles) 1958; M.A. Harvard 1960. Social welfare financing, capital formation and growth: an international comparison. *Harvard*.
- GLEN ALEXANDRIN, B.A. Alberta 1958. Unemployment in Newfoundland, 1949-1961. *Clark*.
- JOHN J. ARENA, B.A. Yale 1958; M.A. 1960. The Pigou effect and saving: a statistical inquiry. *Yale*.
- RICHARD E. ATTIEYEH, B.A. Williams 1958. The determinants of investment in plant and equipment. *Yale*.
- RALPH BEALS, B.S. Kentucky 1958; M.A. Northwestern 1959. Inventories, expectations and the relation between spot and futures markets. *Mass. Inst. Technology*.
- JACK BEN-RUBIN, B.S. Columbia 1954; M.A. Columbia 1959. The economics of rent control. *New York*.
- ROBERT A. BERRY, B.A. Western Ontario 1959. Welfare implications of non-competitive economies. *Princeton*.
- CHARLES L. COLE, B.A. Southern California 1951; M.B.A. Stanford 1955. Income distribution and the social welfare function: a study of theories of distributive justice. *Southern California*.
- ARTHUR D'ANTONIO. Effect of innovational profit as alternative explanation for differences in short and long run saving functions.
- F. TRENERY DOLBEAR, JR., B.A. Williams 1957; M.A. Yale 1958. Estimation of utility functions in risk situations. *Yale*.
- HERMANN ENZER, B.S. Boston 1959; M.A. 1960. Skilled labor: an analysis of a joint product. *Harvard*.

- CHARLES R. FRANK, JR., B.S. Rensselaer Poly. Inst. 1959. Integer programming and factor and product indivisibilities. *Princeton*.
- JAMES W. FRIEDMAN, B.A. Michigan 1959; M.A. Yale 1960. Individual behavior in oligopolistic markets: an experimental study. *Yale*.
- JAMES P. GANDER, B.A. Saint Mary's 1953; M.A. California (Berkeley), 1959. Economics of the growth of the firm. *California (Berkeley)*.
- LEONARD GROENEVELD, B.S. Rhode Island 1951; M.B.A. 1958. An inquiry into the marketing views of Alfred Marshall. *Florida*.
- ASHOK S. GUHA, B.A. Calcutta 1957; M.A. 1959. The theory of capital-labour substitution and disguised unemployment. *Harvard*.
- RICHARD M. HALFYARD, B.A. California (Los Angeles) 1954; M.A. 1959. The stock of consumer durable and aggregate consumption behavior. *California (Los Angeles)*.
- WAHIDUL HAQUE, B.A. Dacca 1954; M.A. 1956. Dynamic programming and resource allocation. *Stanford*.
- HAROLD M. HOCHMAN, B.A. Yale 1957; M.A. 1959. A study of the potential effects of the introduction of accelerated depreciation on investment. *Yale*.
- THOMAS E. HOLLAND, B.S. Tennessee 1957; M.S. 1958. Inquiry into the ethics and economics of interest. *Duke*.
- JOHN H. HOTSON, B.A. Colorado College 1952; M.A. Pennsylvania 1957. International comparisons of the wage share in business income. *Pennsylvania*.
- CHING-YAO HSIEH, B.A. St. John's (Shanghai) 1939; M.A. George Washington 1958. Aggregate demand theory during the 18th century. *George Washington*.
- SEANE J. HUNT, B.S. Miami 1954; M.A. Yale 1958. Income distribution among college graduates and the rate of return on educational investment. *Yale*.
- ANDREW JACKSON, B.A. George Washington 1943; M.A. 1953. Utility value theory in France to J. B. Say. *George Washington*.
- ALFONS JOACHIMOWSKI, L.L.B. Pozan 1928; M.A. New School 1960. Poverty in the doctrines of the classical English economists. *New School*.
- PAL JONAS, B.A. Dean Ferenc Gymn (Budapest) 1940; Dipl. Josef Nador 1948. Spatial competition and strategy of social political decisions. *Columbia*.
- JOE K. KERBY, B.S. Brigham Young 1959; M.B.A. Northwestern 1960. A limited statistical analysis of the effect of aggregate advertising expenditure on the consumption function. *Columbia*.
- ROBERT W. KILPATRICK, B.A. Haverford 1957; M.A. Yale 1958. Shifting of the corporate income tax. *Yale*.
- SAMUEL S. O. LEE, B.B.A. Hawaii 1952; M.B.A. 1959. Price-level adjustment problems in Korea. *Columbia*.
- SEANE MAGE, B.A. Chicago 1951; B.A. City 1953. Law of the falling tendency of the rate of profit. *Columbia*.
- MATITYAHU MARCUS, B.A. Brooklyn 1959. An evaluation of the capital output ratio as a means of forecasting the growth of output. *Brown*.
- VINCENT G. MASSARO, BS. Canisius 1959; M.A. Notre Dame 1960. Karl Marx and the evolution of economic forms. *Notre Dame*.
- MICHAEL D. MCCARTHY, B.Com. Notre Dame 1957. The sources of technical progress. *Southern Methodist*.
- WILLIAM G. NELSON, B.A. Youngstown 1940; M.L. Pittsburgh 1951. Concepts of the firm with especial reference to their roles in economic analysis. *Pittsburgh*.
- CONSTANCE K. NEWSOM, B.A. Hunter 1958. Demand theory in the English classical school. *Tulane*.
- DALE K. OSBORNE, B.A. Kentucky 1959; M.A. 1961. Studies in the theory of oligopoly. *Kentucky*.

- HANS C. PALMER, B.A. California (Berkeley) 1954; M.A. 1955. The Italian entrepreneur in California. *California (Berkeley)*.
- CHARLES S. ROCKWELL, B.A. Redlands 1954; M.A. California (Berkeley). 1961. Speculation and futures markets. *California (Berkeley)*.
- T. K. RYMES, B.A. Manitoba. Some problems in the theory and measurement of capital. *McGill*.
- SARDY HYMAN, B.S. Brooklyn 1958; M.A. 1959. Determinants of corporate savings. *New School*.
- ARJUN SENGUPTA, B.A. Calcutta 1956; M.A. 1958. The implications of increasing returns and external economies for the theory of economic growth. *Mass. Inst. Technology*.
- ROGER H. SPILDE, B.A. Luther 1956; M.A. Iowa 1958. An appraisal of oligopoly and economic growth. *Iowa*.
- ALEXANDER G. VICAS, B.Com. McGill 1960. The lag of unrestricted imitation behind product innovation. *Princeton*.
- WILLIAM H. WALLACE, B.B.S. Mississippi 1955; M.B.A. 1956. The theory and application of regional income determination in the United States. *Illinois*.
- JOSEPH ZRINYI, B.A. Pius College, Hungary; M.A. Montreal. Entrepreneurial behavior in economic theory; an historical and analytical approach. *Georgetown*.

Economic History; Economic Development; National Economies

Degrees Conferred

- NASSAU A. ADAMS, Ph.D. Harvard 1962. Economic growth and the structure of foreign trade.
- ROBERT K. ARNOLD, Ph.D. California (Berkeley) 1961. Theoretical models for projecting the California economy.
- HARVEY AVERCH, Ph.D. North Carolina 1962. Some welfare criteria for underdeveloped areas.
- ELIEZER AYAL, Ph.D. Cornell 1961. Public policies in Thailand under the constitutional regime—a case study of an underdeveloped country.

VACANCIES AND APPLICATIONS

The Association is glad to render service to applicants who wish to make known their availability for positions in the field of economics and to administrative officers of colleges and universities and to others who are seeking to fill vacancies.

The officers of the Association take no responsibility for making a selection among the applicants or following up the results. The Secretary's Office will merely afford a central point for clearing inquiries; and the *Review* will publish in this section brief description of vacancies announced and of applications submitted (with necessary editorial changes). Since the Association has no other way of knowing whether or not this section is performing a real service, the Secretary would appreciate receiving notification of appointments made as a result of these announcements. It is optional with those submitting such announcements to publish name and address or to use a key number. Deadlines for the four issues of the *Review* are February 1, May 1, August 1, and November 1.

Communications should be addressed to: The Secretary, American Economic Association, Northwestern University, Evanston, Illinois.

Vacancies

Labor economists: Department of Labor has openings for work in the fields of wages, manpower, employment, labor and industrial labor conditions and related fields. Salaries range from \$6,435 to \$13,730 depending upon experience and training. To apply, send résumé or Standard Form 57 to the Executive Secretary, Board of U.S. Civil Service Examiners, U.S. Department of Labor, Washington 25, D.C.

Industrial organization, trade regulation, industrial concentration, structure of industry, price behavior: The Antitrust Division of the U.S. Department of Justice has openings for economists in Washington, D.C. Candidates should possess a background of education or experience in above fields. Duties involve the application of economic analysis to the enforcement of the antitrust laws. All positions are within the competitive civil service; entrance salaries range from \$5,355 to \$10,635 per annum. Write: Mr. John W. Adler, Chief, Personnel Office, Department of Justice, Washington 25, D.C.

Agricultural economist: Production economics research; rank and salary determined by education and research but range of \$8,500-\$11,000 possible. Short-term applicants unwanted. Supply information required in Federal Form No. 57. Interested parties apply Director, Land Study Bureau, University of Hawaii, Honolulu 14, Hawaii.

Technical assistant: For its program of technical assistant to the developing countries, the I.L.O. is looking for experts in the formulation and implementation of employment objectives in economic development to be assigned by the I.L.O. to serve as a member either (1) of the staff of a regional economic development institute to be set up in Latin America and later to be set up in Asia and Africa; or (2) of a group of experts advising a government on economic development planning and programming; or a combination of these functions. For details write to the Washington Branch Office, International Labor Office, 917 15th Street, N.W., Washington 5, D.C.

Economics: University teaching appointment in Latin America. Prerequisites: graduate of an accredited college with major in economics and emphasis in the labor field; experience in industry or trade union desirable; prefer applicant working toward advanced degree; native fluency in Spanish; amenable in social situations. Job description: two-year contract on staff of economics department in Latin-American university. Starting salary, \$7,500 to \$8,500, plus allowances, depending upon qualifications. Send résumé.

Economics: Ph.D., or all work completed except thesis, to take charge of area of economics. Rank, associate professor; salary according to education and experience. Write: Dr. T. Hillard Cox, Division of Business Administration and Economics, University of San Diego, San Diego, California.

Regional economics: Ph.D. or M.S. plus four years of research experience. Conduct fundamental and applied research on interdisciplinary problems in fields of regional development and long-range planning. Research on domestic and foreign areas using team approach. Send résumé of education and experience in research to L. G. Hill, Battelle Memorial Institute, 505 King Avenue, Columbus 1, Ohio.

Transportation economics: Ph.D. or M.S. plus four years of research experience. Conduct fundamental and applied research on domestic and foreign problems using interdisciplinary team approach. Send résumé of education and research experience to Battelle Memorial Institute (address above).

Economic planning: Ph.D. or M.S. plus four years of research experience. Conduct fundamental and applied research on area aspects of domestic and foreign problems using interdisciplinary team approach. Send résumé of education and research experience to Battelle Memorial Institute (address above).

Graphic economist: Bachelor's in geography plus two years' experience. Design and draw analytical (nonmathematical) maps and illustrative graphics using latest drafting, reproduction, and printing techniques and processes. Send résumé of education and experience to Battelle Memorial Institute (address above).

Economics: Ph.D. with deep interest in economic research. Position involves analysis of interrelationships between technical developments and the economic environment. The effort includes fundamental research in economics, macroeconomic analysis as an input to long-range planning, and interdisciplinary studies of the sociopolitical implications of the economic impact of changing technology. The ability to communicate in an interdisciplinary atmosphere is essential. Desired detailed résumé of education, experience, and interests (Battelle Memorial Institute; address above).

Economics: Applications are invited for a Lectureship or Senior Lectureship in Economics at the University of New England, Australia. Post involves undergraduate teaching in economic theory and/or money and banking, and research in fields of appointee's own interest. The normal teaching load is about four class hours per week. The Department is of moderate size, at present 12 faculty members. Salary scale for Senior Lecturer: £A2,597 by £A95 to £A3,047; for Lecturer: £A1,777 by £A105 to £A2,482. Status and initial salary according to qualifications and experience. Fare to Australia paid for appointee, wife, and children, plus a baggage allowance. Appointment may be permanent or for three years. In the latter case, £A400 will be paid toward return fares. Further information obtainable from Professor of Economics, University of New England, Armidale, N.S.W., Australia.

Economist: Ph.D. or M.S. plus two or more years of experience in research or evaluation of economic programs. Serve as Chief of an Economics Section. Responsible for preparation of economic base surveys; developing and/or adapting projects of factors affecting economic trends of national, regional, and local scope. Studies, analyzes, and evaluates assembled economic data. Makes recommendations regarding the economic justification for projects under consideration. Send résumé of education and experience, preferably on Government Standard Form 57, which may be obtained at any first class Post Office, to District Engineer, U.S. Army Engineer District, P.O. Box 60, Vicksburg, Mississippi.

Labor economics and statistics: Government agency responsible for studies and programs involving scientific and technical manpower seeks several economics graduates with training and/or experience in labor economics and statistics for positions in Washington, D.C., dealing with work in the area of labor force and employment, utilization and demand. Salary dependent on background and experience; opportunity for promotion. Send résumé or Federal Government Form 57 giving full details.

Transportation economist: Co-operative federal-state-local agency working on comprehensive transportation plans for upstate New York metropolitan areas is seeking an economist to work on its interdisciplinary research and planning team. Examples of work are forecasting regional economic growth and studying investment in transportation networks. Beginning salary \$9,450. Full data processing, computer, and publication facilities. Send résumé, including present salary, to Roger L. Creighton, Director, Niagara Frontier Transportation Study, 79 North Pearl Street, Albany, New York.

Labor market economist: To participate in a youth development program by conductive studies of long-range employment opportunities in the New Haven region and work with school personnel to provide proper training programs—other opportunities. Ph.D. in economics with 2 years of experience; or M.A. with 4 years of experience. Salary \$10,000. New Haven is undertaking a comprehensive action-research program with emphasis upon social services, education, employment, housing and services to the young and elderly. A nonprofit corporation has been established to study and act in these fields. Write: Community Progress, Inc., 270 Orange Street, New Haven, Connecticut.

Business administration: Position to begin September, 1963. Person whose teaching areas would be first-year accounting, management, marketing, finance, and to supervise business seminar in a small liberal arts college. Ph.D. or most requirements completed. Salary dependent upon education and experience. Apply to: Dean David A. Waas, Otterbein College, Westerville, Ohio.

Economics: Position to begin September, 1963. Person to teach principles of economics and several advanced economics courses in a small liberal arts college. Ph.D. or most requirements completed. Salary dependent upon education and experience. Apply to: Dean David A. Waas, Otterbein College, Westerville, Ohio.

Economist: With training and/or experience in regional economic analysis and development. Some knowledge of Canada's Maritime economy desirable but not necessary. Salary to \$8,000, depending on qualifications. Apply to: Director, Extension Department, St. Francis Xavier University, Antigonish, Nova Scotia, Canada.

Public finance, land and forest economics: Forest Service, Department of Agriculture, has opening for work in taxation, preparing ad valorem assessment guides for forest land and timber; also openings for studies of markets and demand for forest products. Forestry training desirable but not essential. Salary range GS-9 (\$6,435) to GS-13 (\$10,635). To apply send résumé or Standard Form 57 to Director, Division of Forest Economics and Marketing Research, Forest Service, U.S. Department of Agriculture, Washington 25, D.C.

Economists Available for Positions

Marketing, statistics, business and industrial economics: Man, 40, married; B.A., M.A., Ph.D. credits completed. Fourteen years of experience in designing and conducting economic and market research projects; contributor of articles to various publications. Seeks research position with business or industry. E1005

Economic theory, history of economic thought, industrial organization, government and business, economic development: Man, 46; Ph.D. Now engaged as economic and marketing consultant. Has had 12 years of teaching experience; 10 years consultation in government and international agencies. Seeks opportunity to teach advanced university courses. Expects appointment of at least associate professorship rank and salary of \$9,500. E1040

Business research: Man, married; Ph.D. Seeks responsible, challenging position in formulation of management information requirements, computer applications to business, performance evaluation, forecasting, long- and short-range planning, and action recommendations. Compensation according to responsibility. E1044

Economic theory, international economics, history of economic thought, labor economics, money and banking, comparative economic systems, economic development, economic fluctuations, public finance, industrial organization, economic history: Man 46; M.A., Ph.D. Years of teaching experience, including graduate teaching; Ford Foundation grant. Now on university faculty. Desires teaching position with a progressive institution. E1052

International economics, underdeveloped areas, particularly Latin American and Middle East, economic development, world regional blocs, international financial organizations: Man, 45, married; M.A., Ph.D. Experienced in government research; 10 years of teaching experience; wide experience in undergraduate courses. Presently teaching in large midwestern university. E1057

International finance, economic development, public finance, monetary and fiscal policy: Man, 33; M.A., Ph.D. requirements except dissertation substantially completed. Fellowships; languages; area concentration Western Europe and Southeast Asia. Four years of research experience in government and research organization. Seeks research position. Willing to relocate. E1064

Economic theory, economic history, economic geography: Man; B.S., M.B.A., requirements for Ph.D. completed except for dissertation. Six years of teaching experience; also business experience. Fellowship recipient. Desires teaching position on the East Coast. Available in fall of 1963. E1066

Principles, economic theory, international economics and monetary policy, economics of underdeveloped countries, business cycles and economics of growth, comparative economic systems: Man, 39, married; M.S., Columbia University, cand. Ph.D., University of Geneva; all requirements for Ph.D. completed except publication of dissertation (publication by major firm expected in 1962). Six years of successful teaching at large state university; Ford Foundation Fellow in Economics and numerous other research awards; many academic honors, including decoration by foreign government; author of 2 books, many articles; finest references. Desires teaching position with opportunity for research at rank and salary commensurate with experience. E1072

Public finance, money and banking, principles, economic thought, government and business: Man, 42; Ph.D. from distinguished midwestern university. Nine years of college teaching experience. Research experience with Federal Reserve System and state government. Learned journal publications. Desires teaching position in university or quality college with research opportunity. E1086

Principles, economic theory, monetary theory, business cycles and forecasting, labor: Man, 28, married, completing Ph.D. course work in June, 1962. Desires teaching position in a college or university in the West or Northwest. Available in June, 1962. Robert L. Peterson, P.O. Box 823, College Station, Washington State University, Pullman, Washington. E1087

Development, Communist and international economics: Man, 41; degree in law and economics, Swiss doctorate in economics, dissertation on Yugoslav development policy. Lived under Communist regime; taught economics in Pakistan; visited India, Burma, Nepal; knows most West European countries; speaks English, German, French, Italian, Russian, Serbo-Croat and Slovene; understands Spanish and other Slavonic languages. Excellent references; several publications. Seeks teaching and/or research post. E1087

Business economics, statistics, public finance, money and banking, corporation finance, planning, cycles, investments: Man, 53; M.A. Successful career as administrator, economic research in government, banking, trade association, manufacturing and consulting; some teaching. Seeks university teaching, director of bureau of business research or administration or combination. E1088

Economics, finance, business administration: Man, 69. To be retired from large eastern university. Latin-American specialist, widely traveled as United Nations and Point Four expert. Fluent in Spanish, German, French; speaking knowledge of Russian. Has long list of publications. Desires position in research or teaching. Available in May, 1963. E1089

Principles of economics, business economics, consumer economics, intermediate economics, government and business, national income economics, transportation: Man, 43; Ph.D. Eight years of teaching and 5 years of business experience. Desires new position which permits concentration in one or two of the above areas. Available in June or September, 1963. E1090

U.S. economic history, international economics, economic theory and history, money and banking, corporation finance: Man, 30; M.A. from foreign university and M.A. from American; candidate for Ph.D. with course work completed. Eight years of banking experience; 5 years of writing and research with U.S. agency; some teaching experience; publications. Fellow, Royal Economic Society, Royal Statistical Society; member, Institute of Bankers, London. Wishes to devote full time to teaching and writing. Available in September, 1962. E1091

Principles of economics, labor, anthropology: Woman; M.A., L.T., Madras University; M.A., Ph.D., 1957, Northwestern University. Twenty-one years of teaching experience (2 years in the U.S.); 2 years as acting principal of college for women; Fulbright Travel Grant; Carnegie Scholarship. At present professor of economics and vice principal of a college for women. Desires position as a visiting teacher or researcher in East or in California. Available for spring and summer session, 1963, or for full year. E1092

International economics, economic theory: Man, 27, married; M.A. in economics from midwestern university. Three years of experience as international economist with U.S. government agency. Desires research, teaching, and/or administrative position with university or college, business, or private organization in Southwest. E1093

Labor economics, money and banking, economic thought, international economics, principles: Man, 26, married; B.B.A., M.A., economics. Fluent in French and Spanish; listed in American Men of Science, Leaders in American Education, 1962 eds. Résumé available. Seeks teaching, research, or administrative position with university or business. Available upon appointment. E1094

Accounting and related subjects: Man, 29, married; M.B.A., C.P.A. Experience includes 3 years of governmental auditing. Desires teaching position. E1095

Theory, mathematical economics, international economics, statistics, public finance: Man, 35, married; Ph.D. Years of successful teaching; good number of articles and book reviews. Desires teaching position at graduate level with research opportunities. Available in June or September, 1963. E1096

Economics, most fields except statistics: Man, over 50; Ph.D. Now teaching in university overseas; academic and practical work in developmental economics; federal service abroad and in Commerce Department. Would join international entity in planning or related capacity; fluent Spanish; no business courses or experience. Prefers teaching in New England, Southwest, Northwest, British Columbia, or Quebec. Available in September, 1963; perhaps earlier if offer is superior to present position. E1097

Finance, investments, real estate, money and banking, forecasting, economics: Man, 49; Ph.D. Unusually successful business experience plus many years of part-time teaching experience. Desires full-time college or university position. E1098

Econometrics, statistics, etc.: Man, 30; M.A., D.Phil. Lecturer at a British university. Seeks summer appointment from July 1, 1963. E1099

Business economics: Mature man, married; Ph.D. Successful economist for leading corporation; previous university teaching experience. Interested in opportunity to develop graduate program for business economists. E1100

Labor economics, labor legislation, collective bargaining, money and banking, history of thought, principles: Man, 39, married; B.S., A.M. Six years of full-time college teaching; research experience. Interested in teaching and/or research position, Northeast or West Coast location. Available in June or September, 1963. E1101

What the world's best telephone service is built on

The foundation of your telephone service is composed of three integrated Bell System activities.

First, there's **research** at Bell Telephone Laboratories to find new telephone services and new ways to improve present services.

Second, there's **manufacturing** by the Western Electric Company in order to produce top-quality telephone equipment at the lowest possible cost.

Third, there's the **operation** of the Bell System performed by the local Bell Telephone Companies at high standards of economy and efficiency.

The results of this three-stage action are improved local and Long Distance service... ever-better telephone instruments... the invention and use of such modern marvels as the Transistor... fast, dependable communications for the nation's defense and for you.

New Books for the Economist

Banking

☐ MORTGAGE LENDING,

Second Edition

By WILLIS R. BRYANT, *Bryant-Johnson Mortgage Company, San Francisco.*

432 pages, \$8.50.

This book provides an integrated and comprehensive introduction to mortgage lending, mortgage banking, the mortgage market and all related activities. There is information on procedures and an appraisal of the social significance of mortgage lending. The new edition incorporates recent developments in the mortgage lending industry and in related activities as well as the essential updating of statistics and other pertinent data.

☐ CASES IN COMMERCIAL BANK MANAGEMENT

By LEONARD MARKS, Jr., *Stanford University*; and ALAN B. COLEMAN, *Harvard University.*

416 pages, \$7.95.

Emphasizing bank management, the 50 case problems present real situations confronting bank managers. Topics covered are commercial banking functions and responsibilities, except trust activities. The case studies introduce the art of banking and broad problems of commercial bank management, including organization and determination of operating policies and objectives, and specific bank management. The last section contains a series of cases dealing with general management problems and strategy considerations in growth and diversification. All cases have been written in the past six years and are drawn from commercial banks throughout the United States.

Economics

☐ NATIONAL INCOME AND THE PRICE LEVEL: A Study in Macrotheory

By MARTIN J. BAILEY, *The University of Chicago.*

320 pages, \$6.95.

This clear and concise discussion of the theory of national income determination

and related theory and policy problems fulfills the need for an integrated and systematic treatment of the subject. The author draws upon all points of view, but especially the Keynesian and Neo-Classical approaches. An encyclopedic approach is avoided, yet all main ideas and issues in the field are thoroughly covered. Numerous illustrations lucidly show the progression of ideas.

☐ ECONOMIC SECURITY IN THE UNITED STATES

By VALDEMAR CARLSON, *Antioch College. Economics Handbook Series.*

240 pages, \$6.50.

This challenging text asks the reader to study the subject of economic security objectively. It is a venture in institutional economics, written to provide a synthesis or a perspective on economic security. The book maintains that the scope and character of economic security in the United States is determined by the imperatives of the market system. Each of the programs of economic security is covered in the context of a functioning economy. The text helps the reader gain an overall understanding of each of the programs of economic security, including private pension plans and welfare programs, by subordinating details of individual acts in favor of historical developments and theoretical interpretations.

☐ INCOME AND WELFARE IN THE UNITED STATES

By JAMES N. MORGAN, HARVEY E. BRAZER, WILBUR J. COHEN, *all of the University of Michigan*; and MARTIN H. DAVID, *The University of Wisconsin.*

544 pages, \$7.95.

A national personal-interview survey is employed to study the distribution and redistribution of income, what determines peoples' incomes, and the intergenerational transmission pattern. The analysis of this survey combines demographic, economic, and social-psychological measurements on each family studied to give a detailed explanation of what determines the economic position of that family.

COLLEGE

McGRAW-HILL BOOK COMPANY, INC.

DIVISION

from McGRAW-HILL ✓

☐ INTERNATIONAL ECONOMIC INSTABILITY

By JOSEPH D. COPPOCK, *Earlham College; currently Director, Foreign Economics Advisory Staff, Office of the Under-Secretary, U. S. Department of State, Washington, D.C. Economic Handbook Series.*

192 pages, \$7.95.

Describes and explains international economic instability, emphasizing the years since World War II with a view to evaluating and devising measures for reducing such instability when it serves no useful purpose. The basic approach is empirical, stressing policy considerations. Contains highly original material in chapters three and four, including some new and interesting factual conclusions about international economic instability during the postwar years. The country approach is stressed, since countries are the primary organizational units for dealing with the problem.

☐ ECONOMIC ANALYSIS FOR ENGINEERING AND MANAGERIAL DECISION MAKING

By NORMAN N. BARISH, *New York University.*

752 pages, \$9.95.

This book discusses the premise that making decisions is the key function in engineering and business activity; and that most of the engineering and management decisions made in industry are, or should be, based upon economic analysis. It presents basic reasoning and methodology of various disciplines important in decision making: economics, accounting, probability and statistics, operations research.

Accounting

☐ ACCOUNTING: The Basis for Business Decisions

By WALTER B. MEIGS, *University of Southern California*; and CHARLES E. JOHNSON, *University of Oregon.*

896 pages, \$7.95.

The fundamentals of accounting are presented in a thorough and comprehensive manner. Distinctive characteristics of the book are emphasis on theoretical accounting concepts and use of accounting to achieve managerial goals. Chapters on "Income Tax" and "Budgeting" included in addition to material usually found in

introductory books. Some problems in every chapter call for interpretation as well as application of principles and procedures. Book includes complete coverage of the basic procedures of accounting, the reasoning underlying their development, the way in which financial statements are derived. Emphasis in both text and problems is on meaning and use of accounting data. Many mechanical details are either omitted or given minimum treatment. Considerable attention devoted to the effect of various business transactions on financial position and periodic income determination.

☐ ACCOUNTING: Intermediate

By WALTER B. MEIGS, *University of Southern California*; CHARLES E. JOHNSON, *University of Oregon*; and THOMAS F. KELLER, *Duke University.*

Available in February, 1963

This second volume of a modern integrated accounting series emphasizes theoretical accounting concepts and the use of accounting data in the decision-making process. The theoretical analysis is closely correlated with the studies and publications of the American Institute of Certified Public Accountants and of the American Accounting Association. Among the outstanding features of this book are thorough exploration of such controversial current topics as executive stock options, allocation of income taxes, and fund flows. The analysis of accounting data is presented from the viewpoint of management concerned with control and decision making and also from the standpoint of outsiders.

Also of interest . . .

☐ TEACHER SHORTAGE AND SALARY SCHEDULE

By J. A. KERSHAW, *Williams College*, and R. N. MCKEAN, *Rand Corporation.*

Available in October.

☐ CREDITS AND COLLECTIONS: Management and Theory, Seventh Edition

By THEODORE BECKMAN, *The Ohio State University.*

640 pages, \$8.50.

OXFORD BOOKS

OF EXCEPTIONAL INTEREST

THEORY OF MONEY

By W. T. NEWLYN. This is a rigorous but brief exposition of monetary theory, narrowly defined, that examines the ways in which monetary policy affects the economy. Throughout the book the author points out the relation between his own analysis and that of the Radcliffe Committee (on the workings of the Monetary System) which, in his view, requires careful interpretation if it is not to mislead. *30 text figures.* \$2.90

MEXICO

Revolution to Evolution, 1940-1960

By HOWARD F. CLINE. The Director of the Hispanic Foundation, Library of Congress, presents the history of the two eventful decades since the exciting days of General Cardenas. He discusses the booming Mexican economy; Mexican political stability, and the famous single-party democracy; agrarian reform; labor movements; education; and international affairs. *19 statistical appendices; annotated select bibliography; 25 maps; 5 diagrams. (Royal Institute of International Affairs)* \$6.75

LAND REFORM AND DEVELOPMENT IN THE MIDDLE EAST

A Study of Egypt, Syria, and Iraq

Second Edition

By DOREEN WARRINER. This Second Edition brings the first, published in 1957, up to date with the exception of the chapter on Iraq, which remains unchanged. A new Postscript on *Agrarian Reform in the United Arab Republic*, based on personal observations in 1961, reviews the later evolution of agrarian reform policy in Egypt and describes the first stages of reform in Syria. \$3.40

THE HISTORY OF THE GOLD SOVEREIGN

By SIR GEORGE DUVEEN and H. G. STRIDE. Here is the story of this world-renowned coin, from the first coin of that name struck in 1489—a hammered coin of great dignity and artistic merit—down to the present day. Written also from the historical and economic points of view, this book stresses the importance of gold coinage in Britain's development of trade with the Continent over the centuries. *24 pages of halftones.* \$4.80

MONEY, BANKING, AND MONETARY POLICY

CLIFTON H. KREPS, Jr., *University of North Carolina*

This important new textbook affords the student a thorough understanding of the national economic significance of monetary and banking policy. Theory is woven throughout in a highly integrated approach to the essential principles of money and banking. Attention is thus focused on the "why" of institutional

processes rather than the "how." The analytical discussion of the history of money and banking development places in true perspective the complex issues of theory and policy. Book contains ample question, problem, and bibliographical material. 1962. 607 pp. \$7.50

PUBLIC FINANCE

EARL R. ROLPH and GEORGE F. BREAK
—both *University of California, Berkeley*

A class-tested presentation of the many theoretical and technical issues involved in public finance at all levels of government. The book effectively demonstrates how economic intelligence can be applied to illuminate the problems of public finance; provides a descriptive-historical analysis of government finance

today and its role in the economy. It draws mainly on American experience in fiscal affairs, but incorporates evidence from other countries where applicable. Current social security programs are examined as well as problems arising from metropolitan growth, fiscal theory and policy, etc. 1961. 586 pp. \$7.50

PERSONAL FINANCE

ELVIN F. DONALDSON and JOHN K. PFAHL
—both *The Ohio State University*

Popular textbook provides an authoritative discussion of the wide range of problems involved in the management of personal finances. In readable, non-technical style, it covers income and budgeting of financial resources, home-buying, uses of credit, etc. Book offers expanded coverage of estate and retire-

ment planning; U. S. Savings Bonds; life, property, casualty, accident and sickness insurance; federal income tax law; etc. Includes a wealth of illustrative material and practical case-problems. Instructor's Manual available. 3rd Ed., 1961. 717 pp. \$7.50

ECONOMIC AND SOCIAL SECURITY

Public and Private Measures Against Economic Insecurity

JOHN G. TURNBULL and C. ARTHUR WILLIAMS, Jr., both
University of Minnesota; and EARL F. CHEIT,
University of California, Berkeley

Second Edition! Designed for students of social insurance and social security, this new book offers a thorough discussion of the various public and private measures for extending economic security. The emphasis is on principles and understanding; abstract discussion of statistical detail is avoided. Following the carefully planned and successful pat-

tern established in the original volume, the Second Edition retains the use of analytical tools in evaluating the private and social insurances and assistances involved in such problems as old age and death, occupational disability and non-occupational illness, unemployment, and sub-standard working conditions. 2nd Ed., 1962. 552 pp. \$8.00

ESPECIALLY RECOMMENDED

PUBLIC POWER IN NEBRASKA

A Report on State Ownership

By Robert E. Firth

Nearly three decades ago Nebraska became the nation's only "all public power" state. In this first definitive account of this development, Dr. Firth gives a forthright analysis of public power management in the state and discusses solutions to problems besetting the various generating and distributing districts. 402 pp., charts, graphs, maps, notes, bibliography, index. \$6.00

HUMAN NATURE IN POLITICS

By Graham Wallas

Introduction by A. L. Rowse

"... one of the most important and original contributions to political thought ... in this century." (A. L. Rowse.) Indispensable collateral reading for every undergraduate student of economics. 314 pp., index. \$1.40

An Outstanding P-H Publication

Robert L. Heilbroner's book offers a new approach to economics. In vivid prose and swift narrative style, he has set forth the basic elements of economic thought in a context at once dramatic and meaningful—the context of history. But Heilbroner has aimed higher than an introduction to economic history. As the reader retraces the sweep of economic evolution, from slave systems and feudalism down through the Industrial Revolution to the present, he is introduced to the essentials of economic theory as the key by which economic history must be understood. Thus history and theory mutually illuminate one another, each rendering the other more significant and intellectually exciting.

The Making of Economic Society

by Robert L. Heilbroner

Heilbroner has not attempted to supplant the standard text. Although *The Making of Economic Society* presents the main outlines of economics in carefully organized fashion, it is intended primarily as a stimulus for more formal study, particularly in the case of economics majors. Few readers, however, will fail to benefit from the lucid exposition of fundamental economic ideas or from their brilliantly revealed relevance to economic issues, past and present. 241 pp., Paperbound: \$2.95, Cloth: \$4.95

**IRWIN
BOOKS**

FOR FALL CLASSES

THE SOVIET ECONOMY: A Book of Readings

By Morris Sarnstein and Daniel R. Lusfeld, both of the University of Michigan

The excellent paperback volume studies planned economies, particularly that of the Soviet Union, and compares them with the American economy.

ECONOMIC POLICY: Readings in Political Economy

Revised Edition

By William D. Crump, University of Illinois, and Emanuel C. Walter, Purdue University

The editors group full-length articles by outstanding economists around the four great problems of an enterprise economy: stability, equality, abundance, and international trade.

CURRENT ECONOMIC PROBLEMS, Third Edition

By Henry William Spiegel, Catholic University of America

Revised and updated, the Third Edition utilizes and shows in operation the most recent advances in economic theory.

READINGS IN CURRENT ECONOMICS, Revised Edition

By Morton C. Grossman, Reed E. Hanson, Chas. S. Hendriksen, Harry E. McAllister, Kerji Okada, all of Washington State University, and William Walman, Business Week.

This revised volume complements the modern contemporary principles texts and enhances student interest and understanding.

THE PRODUCTION FUNCTION IN ALLOCATION AND GROWTH: A SYNTHESIS

By MARVIN FRANKEL*

Two production functions have over recent decades occupied a prominent place in aggregative economics. One of these is the well-known Cobb-Douglas type of function, $P = aK^{\beta}L^{\alpha}$, where P is total output, a is a constant, K and L are the quantities employed of capital and labor, and where the exponents sum to unity. This function has played a central role in efforts to explain the alleged relative stability in the income shares of capital and labor and has inspired an admixture of hope, belief, and skepticism that it summarizes some general and fundamental laws governing production and distribution [4] [6] [11] [12]. The other function is a more elementary one of the form $P = f(K)$ or simply $P = aK$, where a may be interpreted either as the output-capital ratio or, in some contexts, as the reciprocal of the accelerator. This function is commonly found in growth models of the kind made popular by Harrod and Domar.

Each of these functions has virtues which, unfortunately, serve to emphasize the limitations of the other. The Cobb-Douglas type of function makes output dependent on at least two productive factors. It implies diminishing marginal returns to either factor with the other fixed and also diminishing marginal rates of substitution between factors. With both factors variable, it exhibits constant returns to scale, a characteristic which perhaps represents a sound middle ground between the other two alternatives. Not the least of its merits lies in what it asserts about factor rewards. Payment to each factor of its marginal product will exactly exhaust total output.¹ These properties, all funda-

* The author is research professor in the Bureau of Economic and Business Research, University of Illinois. He acknowledges with thanks helpful comments on the paper by Hans Brems, Robert Ferber, Anders Ølgaard, and Robert Resek, and the statistical assistance of Anne Y. Harper.

¹ Of less certain merit is the property of unitary elasticity of substitution whose presence insures that, provided factors are paid at rates corresponding to their marginal products,

mental in economic thinking about resource allocation and income distribution, hold appeal on both theoretical and empirical grounds.

The advantages of the function $P=aK$ lie in a quite different direction. When this function is used in a simple growth model, in which investment (saving) is a constant fraction of output,² results are generated that make rough sense in terms of observed experience. Thus, a rate of net investment of 10 per cent together with an output-capital ratio of one-third will yield in such a model an annual growth rate of about 3 per cent. Economists have found such models attractive because of their relatively simple structure, because of the emphasis they give to capital accumulation as an "engine of growth"—an emphasis with deep roots in economic thought—and because of their pragmatically satisfying results. In consequence they have played a central role during recent years in theories of growth and development.

Unfortunately the production function $P=aK$ has nothing interesting to say about resource allocation or income distribution. Worse than this, as a general statement of the resources required in production, it is positively wrong, as any one-factor production function must be. The limitations of the Cobb-Douglas function, this time in a growth setting, are less transparent but nonetheless weighty. When this function is used in a growth model of the kind just described, with growth in the labor force taken as autonomous, the resulting *long-term* rate of growth in output turns out to equal the rate of growth in the labor force. Growth in output per worker, commonly regarded as the essence of development, is zero, and the rate of investment exerts no effect!³

A second limitation of the Cobb-Douglas function appears when it is fitted to historical data. An improved fit generally is obtainable if the exponents β and α are allowed to vary freely instead of being constrained to equal unity. With some sets of data, the resulting sum of the exponents has differed significantly from unity, an outcome that opens the door to economies and diseconomies of scale and that leads to abandonment of the convenient assumption that factors are paid their marginal products. A reluctance to use the Cobb-Douglas function in its pure form results also from findings like those of M. Abramovitz that for the

factor shares will remain stable. The use of a constant elasticity function, a broader class of linear homogeneous production functions in which the Cobb-Douglas function becomes a special case, opens up interesting possibilities for economic analysis. See [2].

Share stability is not an issue of consequence in the present paper. Although the unitary elasticity property of the Cobb-Douglas function, like others of its properties, affects the particular results obtained at various points, the main line of argument is not dependent on it. For the purpose at hand, moreover, there are advantages in the function's simplicity and familiarity.

² See below pp. 1009-10 for an example of such a model. Substitute $P=aK$ for (5) and neglect (5d) and (5e).

³ See below, p. 1010. Also [14].

United States for the interval from 1869-78 to 1944-53, "The source of the great increase in net product per head was not mainly an increase in labor input per head, not even an increase in capital per head. . . . Its source must be sought principally in the complex of little understood forces which caused productivity . . . to rise" [1].

These considerations have led some economists to try an alternative approach in which the constraint on $\beta + \alpha$ is retained and a time trend added to the production function so that it takes the form $P = ae^{gt}K^\beta L^\alpha$, where g is some constant rate of growth per year [3] [16]. In this form the function may also be used in a growth model to give a long-term growth rate in output per worker of $\frac{g}{\alpha}$.⁴ But this approach leads to the unhappy consequence that growth in productivity takes place independently of growth in the capital stock. Output per worker rises steadily because of the action of forces—variously referred to as technical change, improvements in organization, improvements in the human factor—outside the system and independently of forces within it. This adaptation of the Cobb-Douglas function to a growth setting entails, in a sense, the sacrifice of a satisfactory explanation of growth itself.

There is a great deal of intellectual discomfort in this dilemma. The function $P = aK$, being a one-factor function, is clearly not salvageable as a helpful tool in the allocation-distribution sphere. Moreover, it can be viewed as a special and limiting case of the function $P = aK^\beta L^\alpha$ where $\beta = 1$ and $\alpha = 0$. But one feels intuitively that the Cobb-Douglas function, with its many theoretical virtues, possesses an underlying logic and ought to serve much better than it does in the realm of growth.

In the discussion that follows, a method is advanced for reconciling the two production functions so that the desirable properties of each, but none of the limitations, are retained. It is shown, in effect, that each function is but a special case of a more general function and of a more general way of viewing the economic process in which recognition is given to the relation between the production function for the enterprise and that for the economy. The approach recognizes the indirect as well as the direct effects of changes in resource inputs and ties both sets of effects to those changes. A main conclusion is that the Cobb-Douglas type of function can hold fully in the allocation realm while the Harrod-Domar type of function can simultaneously hold fully for growth. An ancillary conclusion is that there is no need for or necessary virtue in an aggregate production function that possesses some desired set of allocation-distribution properties.

Some implications of the approach for growth models also are explored and the results of preliminary efforts to apply the approach to historical data are presented. As a by-product of the main discussion,

⁴ A derivation is given in the appendix.

the question of the secular stability of the rate of return to capital also is briefly discussed.

I. *Relation Between the Enterprise and the Aggregate Production Functions*

Let us begin by considering an economy made up of a large number of enterprises, each with a production function of the form:

$$(1) \quad P_i = aHK_i^\beta L_i^\alpha$$

where the subscript i denotes the i th enterprise, and P , K , L , and a are defined as before. As before also $(\beta + \alpha) = 1$. The symbol H , to be referred to as the development modifier, is intended to denote the level of development of the economy in which the enterprise operates and is, for the enterprise, a parameter. Its logic is simple. Enterprises in relatively developed or advanced economies are able to produce more with given inputs of capital and labor than enterprises in relatively underdeveloped economies. This is the essence of economic development. If the number of enterprises in the economy is large, as we assume it to be, then no single one of them can, through its own actions, affect the value of H . The choice of a specific measure or index of H will, for the moment, be left in abeyance.

Suppose that the i th enterprise, a "typical" enterprise, produces some fraction, $\frac{1}{n}$ th, of aggregate output. Then aggregate output can be written:

$$(1a) \quad nP_i = naHK_i^\beta L_i^\alpha$$

Given that all enterprises have production functions identical with the typical enterprise's, and since that function is linear and homogeneous, it follows that production of $\frac{1}{n}$ th of aggregate output, P , requires the

employment of $\frac{1}{n}$ th of the totals of each resource, K and L , so that:

$$(1b) \quad K_i = \frac{K}{n}, \quad L_i = \frac{L}{n}$$

and

$$(1c) \quad nP_i = naH \left(\frac{K}{n} \right)^\beta \left(\frac{L}{n} \right)^\alpha$$

which gives for the aggregate production function:

$$(1d) \quad P = aHK^\beta L^\alpha$$

This aggregation procedure implies an economy in which individual enterprises may vary in size (scale) but employ K and L in the same ratio, which is equal to the economy-wide ratio, and produce output in

the same proportion as they employ factors. The assumptions are restrictive but are not, it may be contended, out of keeping with the traditions of economic theory or unreasonable considering the orientation of the discussion.⁵ Similar results can be obtained under much less restrictive assumptions, but not without encumbering the exposition. (See the appendix, Part A.)

It is convenient at this point to introduce a more specific definition of the development modifier, H . A number of expedients might be used to measure it, like birth or death rates, literacy rates, nutritional levels, levels of per capita income, or levels of capital per worker. Without intending to deprecate any of the other alternatives, let us provisionally choose the last of these, which ranks among the more familiar indexes of

development. Explicitly, let $H = \left(\frac{K}{L}\right)^\gamma$, where the exponent γ is a parameter and gives the expression a more general form.⁶

For the economy as a whole H must be treated as a variable rather than a parameter. Like the other variables in the aggregate function, K and L , it reflects the outcome of the actions of all enterprises. When a single enterprise adds, say, to its capital, the level of development is not significantly affected. But when all enterprises do so, the modifier changes. The aggregate production function may now be written

$$(1e) \quad P = a \left(\frac{K}{L}\right)^\gamma K^\beta L^\alpha \\ = a K^{\beta+\gamma} L^{\alpha-\gamma}.$$

Only one more step is needed to complete our synthesis. Suppose—and the empirical validity of the supposition is considered below (see Section IV)—that $\gamma = \alpha$. Then the aggregate function reduces to

$$(1f) \quad P = aK.$$

The nature of this synthesis can be summarized as follows. Production in the typical enterprise is governed by a function of the form (1). Under these conditions the properties of the Cobb-Douglas function hold fully for the enterprise. As the enterprise varies its factor inputs, say accumulating capital in response to market and other opportunities,

⁵ It may be noted that any linear homogeneous production function lends itself to the method of aggregation employed here. The result is always an aggregate function that mirrors the enterprise function.

⁶ It will be noted that the sum of the coefficients, $\beta + \alpha + \gamma - \gamma$, remains equal to unity. This constraint could be eliminated by putting the modifier into the yet more general form $\frac{K^\gamma}{L^{\gamma'}}$, and this procedure is followed in Section IV and in the appendix. Meanwhile, use of the simpler version in this and the subsequent two sections does not affect the conclusions of the discussion in any essential way.

the modifier shifts. The shifts are exogenous for the enterprise in question and reflect the collective impact of the actions of all enterprises as they respond in similar fashion to economic opportunities. The typical enterprise thus remains "in step" with the economy, continuing to employ factors in the same proportion as the (changing) national average. The upshot is that instead of moving along its production function (1), $P_i = aHK_i^\beta L_i^\alpha$, which is an *ex ante* function, the enterprise moves along a realized function which mirrors (1f), namely $P_i = aK_i$.

Figure 1 depicts this situation. The enterprise's movement is resolvable into two components, one to the right along the *ex ante* function and the other an upward displacement to the realized function.

FIGURE 1. *Ex Ante* AND REALIZED PRODUCTION PATHS FOR THE ENTERPRISE WHEN $\gamma = \alpha$ (L_i constant)

It is characteristic of the aggregate function, in which the modifier is a variable, that it internalizes all of the effects on development that are collectively generated by enterprises. Here the term development may be construed broadly to include the several indirect, as distinct from the direct, effects of resource changes. Among these indirect effects are improvements in organization and the quality of labor, technical change, external economies of scale, and better social overhead facilities in the form of transport and communication networks.⁷ As enterprises expand (say) their K_i 's, there is a double impact on the aggregate function: aggregate output rises as a direct result of an increase in one of the factor inputs, and it rises also because the numerator of the modifier has grown. The aggregate function is, in effect, a summation of the realized paths of all enterprises. Provided that $\gamma = \alpha$, the net outcome is as in (1f).⁸

There is no reason to require that an aggregate production function possess properties which accord with our beliefs about the allocation-distribution realm. For it is in the enterprise that factors are employed

⁷ This interpretation is rough. Treatment of H as a parameter for the enterprise implies ignorance by it of all the factors placed in the indirect category. Enterprises will, however, be aware to some extent of these factors and this awareness may play a role in their decisions. This point is treated further in Section III below. An alternative would be to label all factors recognized by the enterprise as direct and all others as indirect. But this treatment would sacrifice any clear distinction among the forces affecting growth and, in mixing the effects from purely quantitative changes in resource inputs with others, would weaken the rationale for using a linear homogeneous production function for the enterprise.

Are the indirect effects neutral or nonneutral in their impact? The answer is that for the *ex ante* enterprise functions they are neutral, for they leave unchanged the relation between the relative marginal productivities of factors and relative factor quantities. But for the aggregate function they are nonneutral.

⁸ The more general point is that any significant departure of γ from zero will result in an *ex ante* relation between inputs and output that is significantly different at the aggregate and the enterprise levels.

The sense in which this approach achieves greater generality differs from that in which the approach of Arrow *et al.* [2] achieve it. The latter drop the assumption of unitary elasticity of substitution, replacing the Cobb-Douglas function by one whose elasticity is constant. This function is then applied at the industry and economy-wide levels in an effort to explain a range of observed data. The present paper proceeds by developing the relation between the micro- and macro-functions. (Although "micro" as here used refers to enterprises, in principle it may denote higher levels of aggregation provided resource allocation decisions at those levels do not by themselves significantly affect the modifier.) The Cobb-Douglas function is retained but is used as a micro-function with one of its parameters, H , dependent on aggregate behavior. The macro-function, which turns out to be different in form from the micro-function, is then developed via the aggregation process. Thus there are two functions, one relevant to the allocation-distribution sphere and the other to the domain of growth.

A synthesis of the enterprise function with the aggregate function $P = aK$ might also be achieved by using, in place of the Cobb-Douglas function, a constant elasticity of substitution function. In general form it may be written $P = (bK^u + cL^u)^{1/u}$ where $u \leq 1$. (See Arrow, *et al.* [2, p. 230], and R. Solow [14, p. 77]. In this case one form of the required modifier, H , would be

$$a \left[b + \left(\frac{K}{L} \right)^{-u} \right]^{-1/u}.$$

and rewards distributed, and here a different, though related, function governs.⁹ By the same token, there is no reason to expect the enterprise function, (1), to give us an accurate account of aggregate growth, since that function accords no recognition to the developmental or indirect effects that enterprises collectively generate. A corollary for growth models is that the production functions employed in them need not possess any particular allocation properties. The use, for example, of a one-factor production function like $P = aK$ may be entirely appropriate and in itself carry no necessary implications, long- or short-run, about the scope for factor substitution and, in so far as it may be related to factor substitution, the equilibrium of the system. Similarly, the use of an aggregate function with nonconstant returns to scale need not carry any implication that factors don't get their marginal products.¹⁰

II. Some Allocation Implications

Consider the marginal products of capital and labor in the enterprise. These take the following form:

$$(2) \quad \frac{\partial P_i}{\partial K_i} = aH\beta K_i^{\beta-1} L_i^\alpha$$

$$(2a) \quad \frac{\partial P_i}{\partial L_i} = aHK_i^\beta \alpha L_i^{\alpha-1}.$$

Let us call these *ex ante* marginal products to distinguish them from a variant to be defined in a moment. As with the Cobb-Douglas function in its more customary form, (2) and (2a) state that the marginal product of either factor varies inversely with its quantity relative to the quantity of the other factor.

Following through on an assumption made earlier that the typical enterprise employs $\frac{1}{n}$ th of each resource so that $\frac{K}{n} = K_i$ and $\frac{L}{n} = L_i$

⁹ It was long ago suggested in connection with the fitting of a production function to cross-sectional data for the manufacturing sector that payments to factors in accord with the marginal products of this function—the interfirm marginal product—did not necessarily imply payments to factors in accord with the marginal products in individual enterprises—intrafirm marginal products. M. W. Reder [12, pp. 262–63]. The reverse proposition in the present article, though its basis is very different, is in principle similar: Payment to factors by enterprises of a wage equal to their marginal products carries with it no necessary implication that factors receive their marginal products as determined from the (historical) aggregate production function.

¹⁰ This is clear if we alter the modifier so that

$$H = \frac{K^\gamma}{L^{\gamma'}} \quad (\text{where } \gamma \neq \gamma') \quad \text{and} \quad P = aK^{\beta+\gamma}L^{\alpha-\gamma'}.$$

The resulting aggregate function may have nonconstant returns to scale even though derived from *ex ante* enterprise functions possessing constant returns to scale.

$\left(\text{and } \frac{K}{L} = \frac{K_i}{L_i}\right)$, then:

$$(2c) \quad \frac{\partial P_i}{\partial K_i} = a \left(\frac{K}{L}\right)^\gamma \beta \left(\frac{K}{n}\right)^{\beta-1} \left(\frac{L}{n}\right)^\alpha = a\beta K^{\beta+\gamma-1} L^{\alpha-\gamma}$$

$$(2d) \quad \frac{\partial P_i}{\partial L_i} = a \left(\frac{K}{L}\right)^\gamma \left(\frac{K}{n}\right)^\beta \alpha \left(\frac{L}{n}\right)^{\alpha-1} = aK^{\beta+\gamma} \alpha L^{\alpha-\gamma-1}.$$

Call these realized marginal products, or perhaps better realized payment functions, to distinguish them from the previous set. The *ex ante* marginal product functions, like the *ex ante* production function, describe the results expected by the enterprise if, with all else unchanged, it varies the quantity of either factor. They relate to what the enterprise "sees" when it contemplates a change in factor proportions. They also indicate what will result if in fact all else remains unchanged. By contrast, the realized payment functions indicate the outcome when the enterprise makes only such changes in factor proportions as keep it "in step" with the economy as a whole—that is with the national average.

This is implicit in the substitution of $\frac{K_i}{L_i}$ for $\frac{K}{L}$. Stated differently, the realized payment functions describe the outcome for the typical enterprise when *all* enterprises seek to move along their *ex ante* marginal product functions. No one enterprise can, through its own actions, affect the development modifier, H , and it is on this supposition that each enterprise (rightly) makes, say, its investment decisions. But when all enterprises accumulate capital, the modifier will change and the realized and *ex ante* outcomes will differ. In this way enterprise production and marginal product functions shift or are transformed, as the economy accumulates capital and alters the proportions in which it employs factors.

Taking again the case where $\gamma = \alpha$, our realized payment functions reduce to

$$(2e) \quad \frac{\partial P_i}{\partial K_i} = a\beta$$

$$(2f) \quad \frac{\partial P_i}{\partial L_i} = aK\alpha L^{-1} \left(\text{or alternatively, } \frac{\partial P_i}{\partial L_i} = aK_i\alpha L_i^{-1}\right).$$

Here labor's return rises more sharply in response to a relative increase in capital than is true of the *ex ante* function. Should capital increase more rapidly than labor, as historically it has, the resulting rise in the real wage rate would be greater than the *ex ante* function indicates. The case

of capital is perhaps more interesting, for it is seen to be constant and independent of relative factor quantities. If one enterprise alone were to add to its capital, it would encounter diminishing returns to that factor. But when all do so, all are beneficiaries of compensatory shifts in the modifier. Figure 2 describes this situation.

There is in this outcome more than a suggestion of observed experience. During the past three-quarters of a century, perhaps much longer, real wage rates have persistently forged upward in the United States as well as some other Western countries. By contrast profit rates, while undergoing wide oscillations, have not exhibited a marked secular

FIGURE 2. *Ex Ante* and REALIZED MARGINAL PRODUCT PATHS
FOR THE ENTERPRISE WHEN $\gamma = \alpha$
(L_i constant)

trend.¹¹ It may be worth noting further that the magnitude of the realized marginal product of capital, as implied by (2e) is within reasonable limits. From (1f) a may be interpreted as the output-capital ratio, a plausible value for which might be .33. Data on capital's share in the national product suggest for the United States a figure for β of perhaps .35. Hence $a\beta$ would equal about 11.5 per cent.

For the aggregate function, (1f) $P = aK$, the marginal products are very different:

$$(2g) \quad \frac{\partial P}{\partial K} = a$$

$$(2h) \quad \frac{\partial P}{\partial L} = 0.$$

These marginal products, like the aggregate function itself, have no meaning for enterprises. Perforce each enterprise makes its decisions in terms of its own *ex ante* function. To a central planner, however, the aggregate function and its derivatives would appear as the *ex ante* functions.¹² Giving recognition to the developmental or indirect effects flowing from changes in factor inputs by enterprises, he would observe a much higher marginal product for capital and a much lower one—zero—for labor. He might rightly decide that the national product would benefit far more from policies stressing higher investment than those emphasizing higher population growth or labor-force participation rates. To him the output-capital ratio would be the true measure of capital's contribution, even though the excess of this figure over $a\beta$, the amount paid to capital by enterprises, accrued wholly to labor.¹³ Similar considerations might, other things equal, lead him to an autarkic position that favored domestic over foreign investment. For investment abroad by domestic enterprises would yield them only the direct return on capital, while investment at home would cause both the direct and indirect benefits to accrue to domestic factors. More simply, investment

¹¹ For the United States, see I. Kravis [9, Table 10, Cols. 8 and 9] who gives estimates of the yield on reproducible assets and total wealth. For Great Britain the yield on consols, for Germany the return on bonds, and for France the yield on securities might be taken as indicative. See [10, charts 53-56] [17, p. 46].

¹² They also would appear to the planner as realized functions, descriptive of the actual outcome when inputs are varied.

¹³ It may be well at this point to note an implication of a modifier of the form K/L . It implies that the level of development, as we have called it, is reversible and will decline if growth in the labor force exceeds that in capital. There may be some truth in this for some underdeveloped economies. But it is probably not a valid assumption for industrialized economies. Having reached a relatively advanced level of development it seems unlikely that such economies would fall away from it under the conditions noted. Accordingly, one might wish to constrain K/L by specifying its movement as monotonic.

abroad raises the level of development abroad, whereas investment at home raises it at home.

III. A Qualification and Extension

The approach we have taken depicts the typical firm as being pushed—from behind, as it were—to successively higher production functions. The firm never anticipates any of the forces that are, in effect, summarized by parametric changes in the modifier, and hence it never foresees the path along which it will actually move. This view is an oversimplification. Firms will at times, in conjunction, say, with changes in their resource inputs and the associated adoption of new technologies, see themselves as moving upward to new production functions and anticipate, to one or another extent, their realized paths of movement. Their experience is a blend of the foreseen and the unforeseen. Hence the question arises whether the approach we have taken is consistent with the possession by firms of partial or complete foreknowledge of their realized production paths.

Suppose the typical firm which, as before, keeps in step with the economy, anticipates its realized path fully. Then its *ex ante* and realized paths will be the same, and it will see its production function not as:

$$(1) \quad P_i = aHK_i^\beta L_i^\alpha$$

but as:

$$(3) \quad P_i = aK_i^{\beta+\gamma} L_i^{\alpha-\gamma}$$

where $K = nK_i$ and $L = nL_i$. When as in Section I we let $\gamma = \alpha$, this becomes simply $P_i = aK_i$.

Its *ex ante* marginal product functions will be the derivatives of (3). Thus for capital the function will be:

$$(3a) \quad \frac{\partial P_i}{\partial K_i} = a(\beta + \gamma)K_i^{\beta+\gamma-1} L_i^{\alpha-\gamma}$$

which may be rewritten approximately:

$$(3b) \quad \frac{\partial P_i}{\partial K_i} = aH(\beta + \gamma)K_i^{\beta-1} L_i^\alpha$$

This last expression differs from the corresponding one for firms without foresight, as given in (2), by the inclusion of γ within the parentheses on the right-hand side.

The production function of the firm with foresight, which is both an *ex ante* and a realized function, gives us no basis by itself for inferring the realized payment functions. There is no necessary connection between the firm's foreseeing its realized production path and foreseeing

its realized payment paths. It may, for example, be aware of and give due recognition to technological changes in its investment decisions and it may even take notice of certain concurrent environmental changes, such as the construction of an improved and cheaper transport network that will be available for its use. But its foresight in these respects does not insure foresight with respect to the realized payment functions—that is, with respect to the outcomes in economy-wide or region-wide factor markets; nor need it affect in a consequential way the outcomes in those markets.

An alternative approach to the problem is to suppose that the enterprise, besides anticipating the indirect effects, anticipates also that their contribution to higher profits will be lost through the forces of competition. This approach permits results identical to those obtained when foresight is assumed to be absent.

Accordingly, the case of foresight does not lead logically to or call for realized payment functions different from those applicable in the case without foresight, namely expressions (2c) and (2d). Payment in accord with these expressions is consistent with both cases and, for both, causes aggregate factor payments exactly to exhaust total product.

To summarize, the line of argument developed in Sections I and II and based upon a typical firm without foresight may be extended to cover the alternative of a typical firm with foresight. The approach taken toward the firm and its production function does not require that managers be completely blind to the forces denoted by the modifier. Possession of some foresight by them is consistent with the same set of realized outcomes presented earlier. Movement by the typical firm along the realized production function, whether the firm foresees the movement or not, may be thought of as the outcome of movement along a linear homogeneous production function that is undergoing transformation; and movement by such a firm along the realized payment functions may be thought of as the outcome of a movement along the derivatives of the same linear homogeneous production function, with the derivative functions undergoing an identical transformation.

IV. *Some Implications for Growth*

A. *The Aggregate Production Function*

The implications for growth of an aggregate production function that incorporates a modifier differ in important ways from those of a similar function in which the modifier is omitted or one in which, instead of the modifier, a time trend is employed. This much is true whether one considers the production function in isolation or as an ingredient in a growth model. Consider first a function of the form $P = ae^{\sigma t} K^{\theta} L^{\alpha}$, where the term $e^{\sigma t}$ describes a time trend that causes output to grow at the rate

g per year. A function of this form has been fitted by Solow [16] to U. S. data for the years 1900-1949, with the results, $g = .015$, $\beta = .35$, $\alpha = .65$. Differentiating with respect to t , dividing by P and substituting these numerical values gives:

$$(4) \quad \frac{P}{P} = .015 + .35 \frac{\dot{K}}{K} + .65 \frac{\dot{L}}{L}.$$

If the quantities of capital and labor employed are constant, output will grow at 1.5 per cent per year. An annual increase of 1 per cent in the stock of capital will raise the rate of growth of output by an additional .35 percentage points, while a 1 per cent increase in the employed labor force will raise it by .65 of a point.

One may be led by this kind of analysis to the conclusion that increases in capital, and hence the rate of investment, do not exercise much influence on the rate of growth in output.¹⁴ The finding that a 1 per cent increase in capital causes output to grow by only about one-third of one per cent stands in sharp contrast to the rather popular view, conditioned and supported by growth models of the Harrod-Domar variety, that output will grow at about the same rate as the growth in capital.

This depressing conclusion about the efficacy, or lack thereof, of investment is sometimes reached by a different but nonetheless related route. Data for the U. S. (private domestic) economy, over the period 1889 to 1957, indicate about a ninefold rise in real output. In the same interval tangible capital rose a little over four times and hours of labor about one and a half times, while the weighed total input of labor and capital combined increased only a little over two times.¹⁵ The figures suggest that increases in capital and labor account for only a fraction of the increase in output and that the contribution of capital alone, when allowance is made for the fact that it represents but a third by weight of value added, has been almost negligible. This approach is, in an essential way, analogous to that which makes output dependent on a Cobb-Douglas function adjusted by a time trend or which fits such a function to historical data. Any increase in output not matched by an equivalent increase in the weighed inputs combined tends to be ascribed to the influence of outside forces unrelated to the resource inputs. The assumptions, of course, constrain the conclusions.

¹⁴ "It seems that the rate of growth which can be attained in a modern industrial economy is not strongly influenced by the investment policy which is applied. Whether investments are high or low, within reasonable limits, national product will increase by 2-3 percent a year, if the volume of employment remains constant. This is mainly because the human factor alone (*i.e., time trend*) is sufficient to ensure a growth of 1.5 percent a year" [3, p. 49]. Aukrust's statistical application was to Norwegian data. His statement assumes an average (and constant) capital-output ratio of 3.5 and a rate of net investment ranging from about 5 to 20 per cent.

¹⁵ Solomon Fabricant [5, Table A]. The data are John W. Kendrick's.

By contrast, consider the aggregate function

$$(1e) \quad P = a \frac{K^\gamma}{L^{\gamma'}} K^\beta L^\alpha$$

where the modifier is given a more general form than in earlier discussion. This formulation does not in itself explain the indirect effects any more than does a time trend. But it differs in two related respects from the latter approach. First it ties the indirect to the direct effects. The indirect effects are implemented through resource changes rather than materializing independently of them. Second, it carries quite different implications about the effects on growth of an increase in a resource like capital.

Differentiating (1e) with respect to time and dividing by P gives:

$$(4a) \quad \frac{P}{P} = \gamma \frac{\dot{K}}{K} + \beta \frac{\dot{K}}{K} + \alpha \frac{\dot{L}}{L} - \gamma' \frac{\dot{L}}{L}.$$

A change in a resource input here has two effects, one direct and the other indirect. Depending on the sign and magnitude of γ and γ' , the indirect effects may either amplify or diminish the direct effects. In the special case, for example, in which $\gamma = \alpha$, a one per cent increase in capital will result in a one per cent increase in output. In this case, and it is a meaningful one, for it conforms rather well to U. S. data for the period 1889 to 1933 (see below, p.1012), investment remains a strategic element in the growth picture.

B. *Growth Models*

The use in a Harrod-Domar type of growth model of a production function with a modifier opens up a number of interesting possibilities some of which have empirical relevance. Let us limit our attention to the following model which differs from one of general familiarity only in the production function that is used:

$$(5) \quad P = aHK^\beta L^\alpha$$

$$(5a) \quad P = C + I$$

$$(5b) \quad I = \frac{dK}{dt} = K$$

$$(5c) \quad C = (1 - s)P$$

$$(5d) \quad L = L_0 e^{\lambda t}$$

$$(5e) \quad H = \frac{K^\gamma}{L^{\gamma'}}.$$

The variables P , K and L have the same meanings as before. The variable I should be understood as denoting net investment, since assets are assumed to be perpetual. The variable C denotes consumption in real terms, the parameter s the net savings ratio, the parameter L_0 the labor force in the initial year, and the parameter λ some constant growth rate of the labor force. The modifier, $H = \frac{K^\gamma}{L^{\gamma'}}$, can be multiplied through in (5) to give for that equation:

$$P = aK^\theta L^\phi, \text{ where } \theta = \beta + \gamma \text{ and } \phi = \alpha - \gamma'.$$

The system of equations can be solved to get the time paths of the variables and their rates of growth. (Part B of the appendix sets forth the procedure.) For the growth rate of output we have

$$(5f) \quad \frac{P_t}{P_t} = \frac{\theta \lambda \phi a s L_0^\phi e^{\lambda \phi t}}{\lambda \phi K_0^{1-\theta} - (1-\theta) a s L_0^\phi + (1-\theta) a s L_0^\phi e^{\lambda \phi t}} + \lambda \phi$$

where $(\theta + \phi) \geq 1$ and $\theta \neq 1$. For $\theta = 1$ the result is

$$(5g) \quad \frac{P_t}{P_t} = a s L_0^\phi e^{\lambda \phi t} + \lambda \phi.$$

In the special case in which the modifier raises the exponent of K to unity and reduces that of L to zero, so that $\theta = 1$, $\phi = 0$ and $P = aK$, we get for (5g):

$$(5h) \quad \frac{P_t}{P_t} = a s.$$

The growth rate is constant and proportionate, being the product of the output-capital ratio and the savings ratio.

Two other cases, more general than the preceding special case, are of interest. Though ordinarily disregarded, they become relevant, as does the special case, when the influence of the modifier is taken into account. Consider first the case where $(\theta + \phi) = 1$ and where θ is relatively large so that ϕ must be relatively small. Then in the very long run the first two terms in the denominator of (5f) become negligibly small and the expression reduces to

$$(5i) \quad \frac{P_t}{P_t} = \frac{\theta \lambda \phi}{1 - \theta} + \lambda \phi = \lambda.$$

The long-run growth rate of output is equal to the growth rate of the labor force, which is a familiar result. Now, however, with θ relatively

large, it is meaningful to ask, How long is the long run? Clearly if θ and ϕ are in the neighborhoods of unity and zero respectively, the outcome ought, at least for a time, to approximate that of the special case (5h), and the savings-investment ratio should be influential during this period. Figure 3, based on equation (5f), illustrates some results for alternative values of θ and ϕ . Growth in the labor force, λ , is taken to be .015 per year. Alternate values of .20 and .10 are assumed for the rate

FIGURE 3. TIME PATHS OF THE GROWTH RATE OF OUTPUT,
GIVEN ALTERNATIVE VALUES FOR θ , ϕ AND s
(a , K_0 and L_0 equal 1)

of saving (equal to the rate of investment), s , while the value of unity is arbitrarily assigned to a , K_0 and L_0 .

In all cases the long-run growth rate in output is the same, .015. However, the movement toward this position occurs at disparate rates. When θ and ϕ take respective values of .35 and .65—which might be thought of as the case in which there is no modifier—the growth rate falls very rapidly toward the .015 level, for all practical purposes reaching it within 100 years. Variation in the rate of investment is significant in the early stages, but this influence rapidly diminishes, all but disappearing within 40–50 years.

As θ rises and ϕ falls, the .015 level is approached more slowly and the rate of investment remains influential for a longer time. With $\theta = .95$, $\phi = .05$ (not shown) the growth rate is still above the .015 level even after

1,000 years, and variation in the rate of investment retains significance for growth for perhaps 200 to 300 years. The results are yet more dramatic for higher values of θ .

The values of .986 for θ and .014 for ϕ are included because (together with a value of α of .321) they represent one set of results for regression analysis as applied to U. S. data for the period 1889–1933.¹⁶ A more extended period running into the fifties might have been selected, but the data do not appear homogeneous for so long a span.¹⁷ The correlation coefficient was .977. If we assign to β and α respective values of .35 and .65 to accord approximately with the distributive shares of capital and labor, then in the context of the approach developed in this paper the regression results imply for the aggregate production function:¹⁸

$$(5j) \quad P_t = .321 \left(\frac{K_t}{L_t} \right)^{.636} K_t^{.35} L_t^{.65}.$$

This case is explored further in Figure 4, but this time, instead of unity, the observed values are used for K_0 and L_0 and the regression-determined value is used for α . A rate of saving of 4.7 per cent is just sufficient to sustain a steady rate of growth at the long-term level of 1.5 per cent. Higher rates of saving generate initial growth rates that

¹⁶ The data are taken from Kendrick [8] Appendix A, Tables III, X, XV relating respectively to gross domestic product, man-hours (civilian) and capital stock (structures, equipment and inventories). The data were first smoothed by means of a moving average. A justification for this or some similar procedure is that the adjustment of these variables to one another is slow, that the relations among them make themselves felt only over the intermediate and longer term, and that the influence of short-term random and cyclical movements that tend to obscure the relations sought should be minimized. A second regression using unadjusted data did not, however, produce markedly different results.

¹⁷ The line of relation between P and K/L moves in a comparatively smooth and steady way until the early thirties and then evidences a definite break. Subsequent movement is along a different path that rises more sharply than in earlier years. Lack of homogeneity as between the pre- and post-'33 periods is reflected also in the behavior of the ratio K/L . It rises continuously through 1933 but then reverses direction and continues downward through 1943. Thereafter it rises steadily, though it does not regain its 1933 level until 1954.

¹⁸ Taking $\gamma = \gamma'$, the function may first be written

$$P_t = a \left(\frac{K_t}{L_t} \right)^\gamma K_t^\beta L_t^\alpha = a K_t^{\beta+\gamma} L_t^{\alpha-\gamma}.$$

Dividing through by L_t gives

$$\frac{P_t}{L_t} = a \left(\frac{K_t}{L_t} \right)^\theta \quad \text{where } \theta = \beta + \gamma.$$

This function was fitted to the series on output, capital and employment referred to in footnote 16. One would expect the fitting of a production function to cross-sectional data to yield different results from those given here, since in that case the level of development and hence the modifier would be held constant. In so far as an aggregate production function has meaning, one might argue, contrary to the customary belief, that it is the historical rather than cross-sectional function that is valid. For unlike the enterprise, the economy cannot alter its resource inputs without generating indirect effects and hence changing the modifier.

FIGURE 4. TIME PATHS OF THE GROWTH RATE OF OUTPUT, GIVEN THE PRODUCTION FUNCTION $P = .322K^{.986}L^{.014}$ AND ALTERNATIVE VALUES OF THE SAVINGS RATIO (s)

are higher and that decline with almost imperceptible slowness toward the long-term rate. Lower rates (not shown) result in initial growth rates below the long-term rate that rise with equal slowness toward it. The growth rate is, for all practical purposes, as sensitive to the rate of investment as in the case where $P = aK$.

Regression analysis covering the later years 1944–54¹⁹ resulted in a somewhat lower value for θ of .89 and a higher value for ϕ of .11. (The value for the α coefficient was .91). The period covered is unfortunately quite short. An idea of the growth implications of this outcome can be gleaned from the approximating case in Figure 3 for $\theta = .90$, $\phi = .10$.

A second case of interest is that where $\theta + \phi$ is not constrained. The long-run growth rate of output is:

$$(5k) \quad \frac{\dot{P}}{P} = \frac{\theta\lambda\phi}{1 - \theta} + \lambda\phi$$

¹⁹ Selection of any earlier initial year for the post-1933 era would have involved the inclusion of years in which the ratio K/L was moving downward. Such years were excluded on grounds that the influence of the modifier is not reversible, at least not in any simple fashion. Once any given level of development has been achieved, it seems unlikely that it would be reduced by a slowing in the growth of the capital stock below that in the labor force.

which now will be greater than λ except when $\theta > 1$.²⁰ Regression analysis for the 1889–1933 period, applied this time without imposing any constraints on $(\theta + \phi)$, gave $\theta = .76$, $\phi = .55$, $a = .09$, with a correlation coefficient of .998. Assigning values to β and α that are approximately equal to the shares of capital and labor in the national product, our implied production function is:

$$(5l) \quad P_t = .09 \frac{K_t^{.41}}{L_t^{.10}} K_t^{.35} L_t^{.65}.$$

For the years 1944–54 regression analysis gave for the parameters:

$$\theta = .92, \phi = .29, a = .19.$$

Limiting attention to the 1889–1933 interval and using the regression-determined values for θ and ϕ in the production function of our growth model, we obtain from (5k) a long-run growth rate of 3.3 per cent, which is more than double the growth rate of the labor force. Figure 5 illustrates the case, once more using observed values for K_0 and L_0 and the regression-determined values for the other parameters. A rate of saving of about 11 per cent yields a growth rate from the outset just equal to the long-term rate. At higher rates of saving the growth rate approaches the long-term rate from above, while at lower rates the long-term rate is approached from below. The rate of saving retains significance for a much shorter period than in Figure 4. Still, it remains as a force to be reckoned with for perhaps 150 to 200 years, a period which is long relative to the span of about 65 years covered by the data.

Given the kind of setting portrayed in Figures 4 and 5, with all of their underlying assumptions, one's judgment on the current importance of the rate of investment for growth depends on where on the time scale one places the present U. S. economy. There is no necessary implication in this kind of analysis that, whatever the economy's present position, it must eventually be dominated by the long-term outcome. Structural changes of one or another sort, discontinuities in the flow of technological change or some other circumstance may from time to time shift the values of one or more parameters, thereby restoring the *status quo ante* and with it the influence of investment. In statistical terms this is to say that the subperiods comprising any extended period may not all be homogeneous.²¹

²⁰ When $\theta > 1$ the first term on the right becomes negative. The long-run rate of growth will then be lower than λ and may be negative.

²¹ It is not claimed of the regression findings offered here that they are either the right ones or the best ones. The data can and have been approached in different ways by different observers, with a variety of results. Moreover, the hazards of correlating time series are well known and the results inherently suspect. Interest in the present findings derives less from any worth they may have as statistics than from their value as a supplement to the main ideas offered in this paper.

FIGURE 5. TIME PATHS OF THE GROWTH RATE OF OUTPUT, GIVEN THE PRODUCTION FUNCTION $P = .089K^{.76}L^{.55}$ AND ALTERNATIVE VALUES OF THE SAVINGS RATIO (s)

In discussions of economic growth the question occasionally arises whether, as an economy matures, there is any tendency for the growth rate to decline. In so far as a long-run terminal rate has any practical meaning, Figure 5 suggests that the approach to it may be either from above or from below, depending on the economy's point of departure. For some economies, therefore, the passage of time may bring a rising growth rate while for others it may bring a decline. In yet other cases it may vary little or not at all.

V. *Some Qualifications and Caveats*

In the writer's view production functions, when used with reference to the typical enterprise or the whole economy, are at best useful fictions. They may suggest underlying reality but can hardly be expected to replicate it. The particular production function and modifier used in the preceding pages as the basis for formal analysis must be understood in this light. Their choice, moreover, is provisional and not necessarily optimal and is not intended to exclude the consideration of other possibilities.

Functions other than the Cobb-Douglas function may be better

suit to the needs both of theory and practice. Two properties of the Cobb-Douglas function are perhaps unduly limiting. One of these is an elasticity of substitution equal to unity. This property has been central to explanations, via an aggregate production function, of an apparent stability in the United States and other countries of labor's share in the national product. The results of recent studies of the data differ as to whether stability in fact has prevailed (cf. [9 *passim*] [13, pp. 196-99]). In any event, it is a contention of this paper that answers to questions concerning income distribution, if they are to be sought in production functions, are better sought at lower levels of aggregation. When one turns to the enterprise and considers the wide diversity among enterprises, both cross-sectionally and over time, in their ability to substitute productive factors for one another, the unitary elasticity assumption seems rather restrictive. One would prefer the greater flexibility of a function whose elasticity might vary from zero upwards, even though this required looking elsewhere for any needed explanation of share stability.²²

A second restrictive property of the Cobb-Douglas function, less consequential than the preceding one, is the requirement that both capital and labor be used in production. Here too greater flexibility would permit accommodation to a wider range of experience. The extremes of the fully automated plan and the use in production of labor alone ought not to be ruled out.

A function of the form $P = (bK^u + cL^u)^{1/u}$, (where $u \leq 1$), is one possible answer [14, p. 77] [2]. This function preserves the features of linearity and homogeneity which, like the other restrictive features of the Cobb-Douglas function, also represent an oversimplification. But on balance they are probably desirable features, for they help to fulfill some theoretical needs and to minimize mathematical complexity. A second possible answer may lie in the use not of a single function but of a set of functions each of which is intended to describe a class of enterprises sharing common characteristics. The mathematics of such an approach are likely to be difficult. But if analytical techniques did not suffice, something might be done with Monte Carlo methods.

Improvement in the modifier, as in the production function proper, also is a distinct possibility. A modifier of the form $\frac{K}{L}$ has the virtue of being simple and of lending itself to an easy economic interpretation. These are useful qualities but they do not alone ensure analytical and empirical adequacy. In principle there is no reason why a term that de-

²² In Appendix A, however, less restrictive assumptions are used in aggregation than are used in Section I. As a result, returns to scale can vary among enterprises and individual elasticities of substitution need not equal unity.

scribes how the production function is transformed need be simple or susceptible of ready economic interpretation. The modifier purports to summarize the indirect effects of quantitative changes in resource inputs. Such effects are varied and include technological change, changes in organization, changes in the contribution of social overhead capital, changes in the quality of labor inputs, and external economies of scale. It is an obvious limitation on the modifier used in this paper that it does not distinguish among these effects. It is also an obvious and related limitation that some of these indirect effects may in fact make themselves felt at times without being accompanied by changes in factor inputs,²³ though adjustments in the concepts of an measuring rods for capital and labor might help to remedy this neglect.

Other types of modifiers might well be developed that would be stronger in these respects and that would meet more efficiently the tests of theory and data. It is worth emphasizing that with modifiers, perhaps more so than with production functions, no single form may suffice to fit all the facts. What works well for one economy over a given period of time may not serve well for a different period or a different economy. A deeper understanding of differences, temporal and regional, in economic development may perhaps come from a fuller knowledge of the forms which modifiers may reasonably be expected to take.

²³ A way of overcoming this problem is by an approach that introduces the indirect effects through a replacement function. Technological change has been handled in this way by Leif Johansen [7] and by R. M. Solow [15]. In the present case, our model in Section V might be expanded to include a replacement function, and the modifier might then be made to depend in some fashion on both the level of the capital stock and its age structure as determined by the rate of replacement.

APPENDIX

A. *The Relation Between Enterprise and Aggregate Production Functions*

For illustration, let the economy consist of three enterprises to be designated by the subscripts j , k , and l . Neglect the modifier for the present. Let the production function of the j th enterprise be

$$(A1) \quad P_j = a_j K_j^{\beta_j} L_j^{\alpha_j}$$

where $P_j = jP$, $K_j = j'K$ and $L_j = j''L$, P , K , and L are the corresponding macro-variables, $j \geq j' \geq j''$ and $0 < (\beta_j + \alpha_j) \leq 1$. Represent the production functions of the k th and l th enterprises in parallel fashion, with

$$j + k + l = j' + k' + l' = j'' + k'' + l'' = 1.$$

Thus a given enterprise may employ different fractions of the totals of each resource and produce a yet different fraction of total output, and it may have increasing, constant or decreasing returns to scale. Substituting the macro- for the micro-variables in each function and expressing each in logarithmic form and summing over all enterprises gives:

$$\begin{aligned} 3 \log P + \log j + \log k + \log l &= \log a_j + \log a_k + \log a_l + \beta_j \log j' \\ &\quad + \beta_k \log k' + \beta_l \log l' + \alpha_j \log j'' \\ &\quad + \alpha_k \log K'' + \alpha_l \log L'' \\ &\quad + (\beta_j + \beta_k + \beta_l) \log K \\ &\quad + (\alpha_j + \alpha_k + \alpha_l) \log L. \end{aligned}$$

Transposing, taking the antilog and rearranging terms gives

$$(A2) P = \left(\frac{a_j a_k a_l (j')^{\beta_j} (k')^{\beta_k} (l')^{\beta_l} (j'')^{\alpha_j} (k'')^{\alpha_k} (l'')^{\alpha_l}}{j k l} \right)^{1/3} K^{(\beta_j + \beta_k + \beta_l)/3} L^{(\alpha_j + \alpha_k + \alpha_l)/3}.$$

Let the first term on the right, which is some constant term, equal a . Let the arithmetic averages of the exponents for capital and labor equal, respectively, β and α . Assume that $\beta + \alpha = 1$, which is less restrictive than assuming the equivalent for each enterprise. Then the resulting linear homogeneous production function is

$$(A3) \quad P = a K^{\beta} L^{\alpha}.$$

This procedure can be extended from an economy of three enterprises to one that covers any number of enterprises.

It is clear that the fractions of resources used and output produced and the extent of economies or diseconomies of scale in each enterprise need not remain constant over time in order that the aggregate function remain stable. All that is required is that the a term and the average of each exponent remain stable, and this stability can prevail if there are compensating changes of various kinds within and among enterprises.

The inclusion of the modifier H in each enterprise function would result in its inclusion also in the aggregate function so that:

$$(A4) \quad P = a H K^{\beta} L^{\alpha}.$$

A less restrictive treatment also is possible by providing that enterprises may be affected by the modifier—or experience the indirect effects of resource changes—in differing degrees. Defining H_j as the modifier applicable to the j th enterprise, we may write

$$H_j = j''' \frac{K^{\gamma_j}}{L^{\gamma_j'}}$$

where j''' , γ_j and γ_j' are the relevant constants for this enterprise. Other enterprises may be treated similarly. The effect on the aggregate function (A4) would be to alter a by the multiplicative inclusion in the numerator of the bracketed term of (A2) of $(j''' k''' l''')$. It would result also in defining γ and γ' (in $H = K^{\gamma}/L^{\gamma'}$) as the respective arithmetic averages of the corresponding parameters for the enterprises.¹

In short, it is possible to develop an aggregate production function of the kind in (A4) by assuming only the form taken by each enterprise's production function. Returns to scale need not be constant for the enterprise, nor need the indirect effects be the same among enterprises.

Let us now define a typical enterprise as that hypothetical i th enterprise

¹ A variant of this approach would be to develop the modifier term directly from each enterprise's micro-variables instead of assuming it initially. This would involve specifying, first, the quantitative relation between an enterprise's micro-variables and the corresponding macro-variables, and second, the relation between the macro-variables and the indirect effects for the enterprise.

which employs $1/n$ th of each resource and produces $1/n$ th of total output, and which has a production function of the same form and parameters identical with those in (A4), so that

$$(A5) \quad P_i = aHK_i^\beta L_i^\alpha.$$

As was shown in Section I, aggregating over an economy of such enterprises yields the aggregate function (A4). Hence the same aggregate function that prevails in an economy of typical enterprises is consistent also with an economy whose enterprises are governed by much less restrictive assumptions.

B. Further Notes

1. Solution for (5f), the growth rate of output or \dot{P}_t/P_t , given the following system of equations:

$$(5) \quad P = aHK^\beta L^\alpha, \quad \text{where } \beta + \alpha = 1$$

$$(5a) \quad P = C + I$$

$$(5b) \quad I = \frac{dK}{dt} = \dot{K}$$

$$(5c) \quad C = (1 - s)P$$

$$(5d) \quad L = L_0 e^{\lambda t}$$

$$(5e) \quad H = \frac{K^\gamma}{L^{\gamma'}}.$$

Letting $\beta + \gamma = \theta$ and $\alpha - \gamma' = \phi$, (5) may be written:

$$(6) \quad P = aK^\theta L^\phi.$$

Inserting (5b) and (5c) in (5a) and the result in (6) we arrive at

$$(7) \quad \frac{dK}{dt} = saK^\theta L^\phi.$$

Inserting (5d) in (7) gives:

$$(8) \quad \frac{dK}{dt} = saK^\theta (L_0 e^{\lambda t})^\phi, \quad \text{and}$$

$$(9) \quad \frac{dK}{K^\theta} = (saL_0^\phi e^{\lambda\phi t}) dt.$$

Now integrate (9):

$$\int \frac{dK}{K^\theta} = saL_0^\phi \int e^{\lambda\phi t} dt$$

which for $\theta \neq 1$ results in:

$$\frac{K^{1-\theta}}{1-\theta} = \frac{saL_0^\phi e^{\lambda\phi t}}{\lambda\phi} + k_1$$

where k_1 is an arbitrary constant of integration. Hence

$$(10) \quad K = \left[\frac{(1-\theta)saL_0^\phi e^{\lambda\phi t}}{\lambda\phi} + k_2 \right]^{1/(1-\theta)}$$

where k_2 is another arbitrary constant. When $t=0$, $K=K_0$ so

$$k_2 = K_0^{1-\theta} - \frac{(1-\theta)saL_0^\phi}{\lambda\phi}.$$

Therefore

$$(11) \quad K_t = \left[K_0^{1-\theta} - \frac{(1-\theta)saL_0^\phi}{\lambda\phi} + \frac{(1-\theta)saL_0^\phi e^{\lambda\phi t}}{\lambda\phi} \right]^{1/(1-\theta)}$$

where K_t denotes the capital stock in year t . Substituting (11) and (5d) in (6) gives:

$$(12) \quad P_t = a \left[K_0^{1-\theta} - \frac{(1-\theta)saL_0^\phi}{\lambda\phi} + \frac{(1-\theta)saL_0^\phi e^{\lambda\phi t}}{\lambda\phi} \right]^{\theta/(1-\theta)} [L_0 e^{\lambda t}]^\phi.$$

Placing (12) in logarithmic form and differentiating with respect to t gives:

$$(13) \text{ and } (5f) \quad \frac{P_t}{P_t} = \frac{\theta\lambda\phi saL_0^\phi e^{\lambda\phi t}}{\lambda\phi K_0^{1-\theta} - (1-\theta)saL_0^\phi + (1-\theta)saL_0^\phi e^{\lambda\phi t}} + \lambda\phi$$

which in the very long run reduces to:

$$(14) \quad \frac{P_t}{P_t} = \frac{\theta\lambda\phi}{1-\theta} + \lambda\phi.$$

In the special case where $\theta=1$, return to (9) and divide through by dt to get:

$$(9a) \quad \frac{\dot{K}_t}{K_t} = saL_0^\phi e^{\lambda\phi t}.$$

Differentiate (5d) with respect to t and divide by L_t to get

$$(9b) \quad \frac{\dot{L}_t}{L_t} = \lambda.$$

Differentiate (6) with respect to t and divide by P_t to get:

$$(9c) \quad \frac{P_t}{P_t} = \theta \frac{\dot{K}_t}{K_t} + \phi \frac{\dot{L}_t}{L_t}.$$

Substitute (9a) and (9b) in (9c), so that:

$$(15) \text{ and } (5g) \quad \frac{P_t}{P_t} = saL_0^\phi e^{\lambda\phi t} + \lambda\phi.$$

2. A slight modification in the general solution will give the growth rate in output when a time trend is added to the production function. Rewrite (6) in the form:

$$(6a) \quad P = ae^{\theta t} K^\theta L^\phi$$

where g is some growth rate per year because of the time trend. Inserting (5b) and (5c) in (5a) and the result in (6a) gives instead of (7)

$$(7a) \quad \frac{dK}{dt} = sae^{\theta t} K^\theta L^\phi.$$

Inserting (5d) in (7a) then gives instead of (9):

$$(9d) \quad \frac{dK}{K^\theta} = (saL_0^\phi e^{(g+\lambda\phi)t}) dt.$$

Carrying through this change in succeeding steps changes the long-run growth rate (14) to:

$$(14a) \quad \frac{P_t}{P_t} = \frac{\theta(g + \lambda\phi)}{1 - \theta} + \lambda\phi + g.$$

If the modifier is neglected, i.e. equals unity (so that $\theta = \beta$ and $\phi = \alpha$), then (14a) reduces to:

$$(14b) \quad \frac{P_t}{P_t} = \frac{g}{\alpha} + \lambda$$

and output per worker grows at the rate:

$$(14c) \quad \frac{\left(\frac{P}{L}\right)_t}{\left(\frac{P}{L}\right)_t} = \frac{g}{\alpha}.$$

ENTRY, GIBRAT'S LAW, INNOVATION, AND THE GROWTH OF FIRMS

By EDWIN MANSFIELD*

Because there have been so few econometric studies of the birth, growth and death of firms, we lack even crude answers to the following basic questions regarding the dynamic processes governing an industry's structure. What are the quantitative effects of various factors on the rates of entry and exit? How well can the growth of firms be represented by Gibrat's law of proportionate effect? What have been the effects of successful innovations on a firm's growth rate? What determines the amount of mobility within an industry's size structure?¹

This paper provides some tentative answers to these questions. First, it constructs some simple models to estimate the effects of an industry's capital requirements, profitability, and other such factors on its entry and exit rates. Second, it investigates how well Gibrat's law of proportionate effect can represent the growth of firms in each of the industries for which we have appropriate data. Although this law has played a prominent role in models designed to explain the size distribution of firms, it has been tested only a few times against data for very large firms. Third, we estimate the difference in growth rate between firms that carried out significant innovations and other firms of comparable initial size. The results help to measure the importance of successful innovation as a cause of interfirm differences in growth rates, and they shed new light on the rewards for such innovations. Fourth, the paper presents and tests a simple model to explain interindustry and

* The author is associate professor of economics at Carnegie Institute of Technology. This paper, a preliminary version of which was read at the August 1961 meetings of the Econometric Society, will be reprinted as a Cowles Foundation Paper. The work on which it is based is part of a larger project on technical change and economic growth, supported by the Office of Economic and Statistical Studies of the National Science Foundation, by a Ford Foundation Faculty Research Fellowship, and by the Cowles Foundation for Research in Economics at Yale University. The paper has benefited from discussions with D. Fink, J. Muth, and N. Seiber. My thanks also go to G. Haines and D. Remington for their assistance and to various companies for data.

¹ With regard to the effects of various factors on the rates of entry and exit, there has been considerable theorizing [4] [14] [21] [30] and a few relevant empirical studies [4] [7], but there has been no systematic attempt to estimate the quantitative effect of various factors. With regard to the growth of firms, there have been several studies of Gibrat's law [11] [13] [15] [27] based only on the largest firms (one of which dealt in part with the determinants of the amount of mobility) and an analysis [8] of the size structure of the largest firms in the economy. There are no previous studies (as far as I know) of the effects of innovation on a firm's growth rate.

temporal differences in the extent to which firms change relative positions in the size distribution.

I. *Determinants of Rates of Entry and Exit*

A. *Entry, Profitability, and Capital Requirements*

Entry can be defined as the net change in the number of firms in an industry. Alternatively, it can be defined as the extent to which new owners of productive facilities become established in an industry either through the construction of new plants or the purchase of existing firms. Each concept has its own set of uses. The first concept is useful in analyzing problems regarding market structure and industrial concentration, since the number of firms in an industry is a significant factor in such problems. The second concept is useful in measuring the ease with which new entrepreneurs can become established in an industry and the extent to which they do so. For this purpose, it would be misleading to ignore those that entered by purchasing existing concerns.²

The second of these concepts is employed in the present subsection; the first will be employed in the next one. Regardless of which concept is used, perhaps the most obvious measure of the amount of entry into the i th industry during the t th period is E_{it}' —the number of firms that entered during the period as a proportion of the number of firms in the industry at the beginning of the period. But the available data force us to use E_{it} —the number of firms that entered during the period and survived until the end as a proportion of the original number of firms. Since E_{it}' and E_{it} should be highly correlated, this discrepancy is probably not too important for our purposes.³

Letting C_{it} be the investment required to establish a firm of minimum

² Of course, the second concept of entry is somewhat slippery, since it is sometimes difficult to define and detect a significant change in the ownership of a firm. This is particularly true in the case of large companies. In practice, we generally use changes in company names as indicators of changes in ownership (see the Appendix), but this is very crude. This problem also occurs in the next subsection and in Sections II and III.

A third definition of entry would be useful for some purposes. This would measure the number of firms that entered with new plant, regardless of the number of firms that scrapped their plant during the period. That is, it would be a gross measure of entry. Bain's discussion [4, p. 4ff.] generally runs in these terms. The available data do not permit us to measure this gross concept of entry. See the Appendix.

³ Other measures might be used: e.g., the absolute number of entrants. But the establishment of two new firms would seem to mean one thing if there previously were two firms and something else if there previously were 100. Moreover, one would expect that ease of entry would be directly related to the number of firms in the industry [23]. Although it is somewhat arbitrary, it seems sensible to follow the Department of Commerce's procedure [7] and to normalize in this way for the original number of firms.

The size of the entrants—as well as their number—might be very important for some problems. Although we ignore this aspect of the problem, it could be included fairly easily. Note too that, in comparisons of the values of E_{it} , differences in length of the period might be important. Although we tried to obtain periods of equal length, this was not always feasible. However, when introduced into equations (3), (7), and (16), this factor has no significant effect on E_{it} , R_{it} , or P_{it} . See Section IV A.

efficient size in the i th industry during the t th period and letting Π_{it} be the average ratio of the rate of return in the i th industry to that in all manufacturing during this period, we assume that

$$(1) \quad E_{it} = f(\Pi_{it}, C_{it}, \dots).$$

Increases in Π_{it} —because of their presumed effect on profit expectations—make entry more attractive, and increases in C_{it} make it more difficult. Thus, E_{it} should be directly related to Π_{it} and inversely related to C_{it} .⁴

More specifically, since the effects of these variables are likely to be multiplicative, we assume that

$$(2) \quad E_{it} = \alpha_0 \Pi_{it}^{\alpha_1} C_{it}^{-\alpha_2} Z_{it},$$

where Z_{it} is a random error term and the α 's are presumed to be positive. To estimate the α 's, data are needed on E_{it} , Π_{it} , and C_{it} . Table 1 shows the values of E_{it} during various periods in the history of the steel, petroleum refining, rubber tire, and automobile industries. It also contains corresponding estimates of Π_{it} and C_{it} , the latter being based on Bain's figures [4] and the assumption that the ratio of the minimum efficient size to the average size of firm remained constant over time in each industry. Although these data are very rough they should be useful first approximations.⁵

Having only the transition matrices in the Appendix, we had no choice but to use E_{it} . So long as the survival rate for new firms is relatively independent of E_{it}' or positively correlated with it, E_{it} should be a reasonably good surrogate. Moreover, if one believes that we should only be concerned with entrants that survive for some specified length of time, E_{it} may be closer to what we want than E_{it}' . Finally, E_{it} has the advantage that it equals $D_{it} + R_{it}$. See Section I B.

⁴ As a first approximation, it may not be too unreasonable to assume that the profit expectation of potential entrants during the period is a function of Π_{it} . But many other factors are obviously of importance—the variability of the industry's profits during the period, the absolute level of profits, the probability that new processes or related new products will be developed, the outlook with regard to factor prices, etc. Note too that C_{it} may vary, depending on whether the entrant is an existing firm in a related industry or an entirely new enterprise; that C_{it} should be measured in real terms; and that the effect of C_{it} will depend on the ease with which a given amount of capital can be obtained.

Equation (2) should be much more effective in explaining changes in the number of new firms with new plant than changes in the numbers of firms that are bought. For example, if Π_{it} is relatively high, relatively few firms may be sold. But, since new firms with new plant are a large percentage of the total number of entrants included in E_{it} (about two-thirds of the total in recent years, according to [7]), equation (2) is a reasonable first approximation. (However, one might argue from this that the error term is additive.) Unfortunately, the data are such that one cannot treat the entrants with new plant separately from those that bought existing plant.

⁵ The Appendix describes the data on entry for each industry and explains how the data regarding C_{it} and Π_{it} were derived. It also points out the difficulties in these measures. I suspect that the true values of C_{it} (and $\bar{S}_{it}/\bar{S}_{it}$) for petroleum in 1921-27 and 1927-37 were substantially lower than those shown in Table I and that the true values of C_{it} (and $\bar{S}_{it}/\bar{S}_{it}$) for steel in 1916-26 and 1926-35 were somewhat higher than those shown in Table I. Errors of this sort, assuming they are randomly distributed, are taken into account in the analysis below.

Taking logarithms of both sides of equation (2) and using these data to obtain least-squares estimates of the α 's, we find that

$$(3) \quad \ln E_{it} = .49 + 1.15 \ln \Pi_{it} - .27 \ln C_{it} \quad (.43) \quad (.14)$$

where the quantities in parentheses are standard errors and $\ln Z_{it}$ is omitted. As one would expect, there is considerable variation about equation (3), the coefficient of correlation (corrected for degrees of freedom) being about .70 (Figure 1). The residuals reflect the effects of dif-

ferences in the capacity of a firm of minimum efficient size as a per cent of the total market, availability of raw materials, and other important factors that are omitted.⁶

The estimates of α_1 and α_2 have the expected signs and are both statistically significant (.05 level). Because of the small number of ob-

⁶ For an elementary account of some of the factors omitted here, see [24]. For a discussion of the automobile industry, see [31]. Of course, the influence of the Second World War (with controls of various sorts) should not be overlooked either.

servations, they have fairly large standard errors, and because of errors in the exogenous variables and the probable effects of $\ln E_{it}$ on $\ln \Pi_{it}$ (cf. Section IV A), they are probably biased somewhat toward zero. But despite these limitations, they shed new light on the effects of Π_{it} and C_{it} on E_{it} . For example, if the bias is in the expected direction, one can be reasonably sure that the average value of E_{it} would increase by at least 60 per cent if Π_{it} doubled and that it would decrease at least 7 per cent if C_{it} doubled. Lower bounds of this sort are obviously useful.⁷

B. Exit Rates and Changes in the Number of Firms

This subsection estimates the effects of several factors on the rate at which firms leave an industry, and it takes up the effects of these, and related, variables on the amount of entry defined in terms of changes in the number of firms—the first of the two concepts of entry defined at the beginning of this section. We use R_{it} —the proportion of firms in the i th industry at the beginning of the t th period that had left by the end—as a measure of the exit rate. Both firms that scrapped their plant and those that sold out are counted as departures.

Letting $R_{it}(S)$ be the proportion of firms of size S (at the beginning of the period) that left during the period, we assume that

$$(4) \quad R_{it}(S) = g(S/\hat{S}_{it}, \Pi_{it}, \dots),$$

where \hat{S}_{it} is the minimum efficient size of firm at the beginning of the period. As a firm becomes smaller relative to the minimum efficient size, its chance of survival decreases; and as the industry becomes less profitable relative to others, firms become more likely to leave. Thus, $R_{it}(S)$ should be inversely related to both S/\hat{S}_{it} and Π_{it} .⁸

Since their effects are likely to be multiplicative, we assume that

$$(5) \quad R_{it}(S) = \nu_0 (S/\hat{S}_{it})^{-\nu_1} \Pi_{it}^{-\nu_2} Z'_{it}$$

⁷ The tests described above are one-tailed tests—which are appropriate here. Our primary purpose is to estimate the effects of Π_{it} and C_{it} on E_{it} , rather than to see if they have any effect. They almost certainly do have an effect but research to date provides little or no clue regarding its magnitude.

For a discussion of the biases due to measurement errors and least-squares, see Section IV A and note 31 in particular. If there were no bias, the likelihood that the lower bounds in the test would be exceeded would equal .85. Given the probable bias, it should be much higher.

The percentage change in the average value of E_{it} , given a doubling of Π_{it} , is $2^{\alpha_1} - 1$. The effect of doubling C_{it} is given by substituting $-\alpha_2$ for α_1 . Of course, one could get lower bounds for the effects of a 10, 20, . . . per cent change in Π_{it} and C_{it} in exactly the same way.

⁸ Of course, the sale of a firm need not mean that it was a failure. Equation (4) is likely to represent the scrapping or abandonment rate better than the rate at which firms are sold. But the former is likely to be a large part of the total and hence equation (4) is likely to represent R_{it} fairly well. The data are such that firms which scrapped their plant cannot be separated from those that sold out. See the Appendix.

where Z'_{it} is a random error term and the ν 's are presumed to be positive. Letting $\rho_{it}(S)$ be the probability that a firm in the i th industry at the beginning of the period is of size S and assuming that the distribution of firms by size is log-normal,⁹ we have

$$(6) \quad R_{it} = \int_0^\infty R_{it}(S) \rho_{it}(S) dS = \nu_0 \left[\int_0^\infty (S/\hat{S}_{it})^{-\nu_1} \rho_{it}(S) dS \right] \Pi_{it}^{-\nu_2} Z'_{it},$$

$$R_{it} = \nu_0 [\bar{S}_{it}/\hat{S}_{it}]^{-\nu_1} (1 + V_{it}^2)^{\nu_1(\nu_1+1)/2} \Pi_{it}^{-\nu_2} Z'_{it}$$

where \bar{S}_{it} is the mean and V_{it} is the coefficient of variation of the distribution of firm sizes.

Table 1 contains rough estimates of R_{it} , $\bar{S}_{it}/\hat{S}_{it}$, and V_{it} .¹⁰ Taking logarithms of both sides of equation (6), we can use these data to obtain least-squares estimates of the ν 's. The results are

$$(7) \quad \ln R_{it} = -1.68 - .41 \ln (\bar{S}_{it}/\hat{S}_{it}) + .10 \ln (1 + V_{it}^2) - .60 \ln \Pi_{it},$$

(.14)
(.25)
(.33)

where the quantities in parentheses are standard errors and $\ln Z'_{it}$ is omitted. For simplicity, the coefficient of $\ln (1 + V_{it}^2)$ was not constrained to equal $\nu_1(\nu_1+1)/2$ —although this constraint would have resulted in somewhat better estimates of the ν 's. Figure 1 shows that there is considerable variation about equation (7), the coefficient of correlation (corrected for degrees of freedom) being .70.¹¹

The estimates of ν_1 and ν_2 have the correct signs and are statistically significant. Although they contain fairly large sampling errors and are probably biased somewhat toward zero (because of errors in the exogenous variables and the probable effects of $\ln R_{it}$ on $\ln \Pi_{it}$), they provide useful information regarding the effects of $\bar{S}_{it}/\hat{S}_{it}$ and Π_{it} on R_{it} . For example, if the bias is in the expected direction, one can be reasonably sure that the average value of R_{it} would decrease by at least 15 per cent

⁹ The log-normal distribution seems to provide a reasonably good (but by no means perfect) fit to the distribution of firms by size. See [13]. Note that we assume only that it is a serviceable approximation from an empirical point of view. Some other distribution (e.g., the Yule distribution) may be more appropriate, but, if it can be approximated by a log-normal, this is good enough for present purposes. The Appendix gives the units in which a firm's size is measured.

¹⁰ The sources and limitations of the data regarding R_{it} , $\bar{S}_{it}/\hat{S}_{it}$, and V_{it} are discussed in the Appendix.

¹¹ The residuals reflect the effects of various important variables that are omitted—the extent to which the plants in the industry can be adapted for other uses, the adaptability and mobility of the management and the work force, the liquidity of the firms, the durability of their equipment, the rate at which costs rise when firms are less than minimum efficient size, etc.

if Π_{it} or $\bar{S}_{it}/\hat{S}_{it}$ doubled. Lower bounds of this sort can easily be computed for the effects of other percentage increases in Π_{it} or $\bar{S}_{it}/\hat{S}_{it}$.¹²

We are now in a position to consider the first, and probably for most purposes the more important, definition of entry. A reasonable measure in this case is D_{it} —the change in the number of firms during the period as a proportion of the number at the beginning. Since the number of firms bought during the period must equal the number sold,

$$(8) \quad D_{it} = E_{it} - R_{it}.$$

Taking antilogs of both sides of equations (3) and (7), multiplying the resulting right-hand-side of each equation by $e^{\sigma^2/2}$ (where σ^2 is the variance of Z_{it} or Z'_{it}) to obtain an unbiased estimate of E_{it} or R_{it} , and inserting the results into equation (8), we can estimate the change in the number of firms, given that the values of Π_{it} , C_{it} , $\bar{S}_{it}/\hat{S}_{it}$, and V_{it}^2 are given.

Of course, such estimates are likely to be rough because of the crudeness of the estimates of the α 's and ν 's and the likelihood that there will be considerable variation about the expected value of D_{it} . (In the 12 cases for which we have data, the correlation between the actual and computed values of D_{it} is .60.) Nonetheless, they may be of use as first approximations in estimating D_{it} and in estimating the effects of changes in Π_{it} , C_{it} , $\bar{S}_{it}/\hat{S}_{it}$ and V_{it}^2 on the average value of D_{it} .

Two further points should be noted. First, it would be preferable to combine equations (2) and (6), obtain D_{it} as a function of Π_{it} , C_{it} , etc., and estimate the α 's and ν 's all at once. But the difference between equations (2) and (6) is awkward to work with. [Perhaps future work will show that some other form of equations (2) and (6) that is more convenient in this respect will fit as well.] Second, the empirical results in this section, like those in Section III, pertain to periods of 7–10 years. They should not be applied to periods much longer or shorter than this.

II. *The Process of Firm Growth*

A. *Gibrat's Law and the Growth of Firms*

Gibrat's law is a proposition regarding the process of firm growth. According to this law, the probability of a given proportionate change in

¹² The procedure used to obtain these figures is just like that described in note 7. Again, our primary purpose is to estimate the effects of the exogenous variables, not to test whether they have any effect. Almost certainly, they have some effect on R_{it} .

This model also suggests a technique for estimating the minimum efficient size of firm in an industry. Suppose that \hat{S}_{it} , rather than R_{it} , were regarded as the "dependent" variable. If data regarding R_{it} , \bar{S}_{it} , Π_{it} and V_{it}^2 were obtained for some new industry or time period, they could then be used to estimate \hat{S}_{it} . This technique is likely to be rough, but some work might be carried out to see how accurate it is and to sharpen it. Of course, this presumes that the

size during a specified period is the same for all firms in a given industry—regardless of their size at the beginning of the period. For example, a firm with sales of \$100 million is as likely to double in size during a given period as a firm with sales of \$100 thousand. Put differently, Gibrat's law states that:

$$(9) \quad S_{ij}^{t+\Delta} = U_{ij}(t, \Delta) S_{ij}^t,$$

where S_{ij}^t is the size of the j th firm in the i th industry at time t , $S_{ij}^{t+\Delta}$ is its size at time $t+\Delta$, and $U_{ij}(t, \Delta)$ is a random variable distributed independently of S_{ij}^t .

Since this law is a basic ingredient in many mathematical models designed to explain the shape of the size distribution of firms and since this law has interesting implications regarding the determinants of the amount of concentration in an industry, some importance attaches to whether or not it holds. This section provides tests based on data for practically all firms—large and small—in three individual industries: the steel, petroleum, and rubber tire industries. The automobile industry is omitted because, with only a handful of firms, it is unlikely to provide much evidence regarding a proposition of this sort.¹³

A simple way to test Gibrat's law is to classify firms by their initial size (S_{ij}^t), compute the frequency distribution of $S_{ij}^{t+\Delta}/S_{ij}^t$ within each of these classes, and use a χ^2 test to determine whether the frequency distributions are the same in each class. We rely heavily on this test, but supplement it with others. The basic data used in these tests are described and presented in the Appendix.

Gibrat's law can be formulated in at least three ways, depending on the treatment of the death of firms and the comprehensiveness claimed for the law. First, one can postulate that it holds for all firms—including those that leave the industry during the period. If we regard the size (at the end of the period) of each of these departing firms as zero (or approximately zero), this version can easily be tested. The results—shown in Table 2—indicate that it generally fails to hold. In seven of the ten cases, the observed value of χ^2 exceeds the critical limit corresponding to the .05 significance level.¹⁴

Why does this version of the law fail to hold? Even a quick inspection of the transition matrices in the Appendix shows one principal reason. The probability that a firm will die is certainly not independent of its

long-run average cost curve is J-shaped and consequently that a minimum efficient size of firm exists in the new industry. For another technique that is somewhat similar in spirit, see Stigler [29].

¹³ For a discussion of the use of Gibrat's law in explaining the size distribution of firms, see [12] [13] [27]. For previous tests, see also [11] [15]. In connection with [27], see note 17.

¹⁴ The size classes and the cut-off points for $S_{ij}^{t+\Delta}/S_{ij}^t$ used in these tests are described in the Appendix.

TABLE 2—OBSERVED VALUE OF χ^2 CRITERION, ESTIMATED SLOPE OF REGRESSION OF $\ln S_{ij}^{t+\Delta}$ ON $\ln S_{ij}^t$, AND RATIO OF VARIANCES OF GROWTH RATES OF LARGE AND SMALL FIRMS, STEEL, PETROLEUM, AND RUBBER TIRE INDUSTRIES, SELECTED PERIODS.^a

Item	Steel				Petroleum				Tires	
	1916-1926	1926-1935	1935-1945	1945-1954	1921-1927	1927-1937	1937-1947	1947-1957	1937-1945	1945-1952

Large firms only	.63	161.00 ^b	.90	8.50 ^b	3.50	7.75 ^b	4.00 ^b	3.6 ^b	39.25 ^b	8.67

^a Symbols: S_{ij}^t is the size of the j th firm in the i th industry at time t , and $S_{ij}^{t+\Delta}$ is its size at time $t+\Delta$. For the classification of firms by size and the classification of $S_{ij}^{t+\Delta}/S_{ij}^t$ used in each industry in the χ^2 tests, see the Appendix. The number of degrees of freedom equals $(a-1)(b-1)$ where a is the number of size classes and b is the number of classes of $S_{ij}^{t+\Delta}/S_{ij}^t$ in the contingency table.

^b For χ^2 criteria and ratios of variances, this means that the probability is less than .05 that a value would be this large (or larger) if Gibrat's law held. For estimated slopes, this means that they differ significantly from unity (.05 significance level).

^c The number of firms in each regression is shown under "Number of firms."

^d The firms regarded as "small" and "large" in the first row are as follows: In steel, small firms have 4,000-16,000 and large firms have 256,000-4,096,000 tons of capacity. In petroleum, small firms have 500-999 and large firms have 32,000-511,999 barrels of capacity. In tires, small firms have 80-159 and large firms have 640-5,119 employees. The firms regarded as "small" and "large" in the second row are described in note 18.

Source: See the Appendix.

size. In every industry and time interval, the smaller firms were more likely than the larger ones to leave the industry. For this reason (and others indicated below), this version of the law seems to be incorrect.¹⁵

Second, one can postulate that the law holds for all firms other than those that leave the industry. Hart and Prais [13] seem to adopt this version. Omitting such firms, we ran another series of χ^2 tests, the results of which are shown in Table 2. In four of the ten cases, the evidence seems to contradict the hypothesis, the observed value of χ^2 exceeding the limit corresponding to the .05 significance level.

To see why this version must be rejected, note that equation (9) implies that

$$(10) \quad \ln S_{ij}^{t+\Delta} = V_i(t, \Delta) + \ln S_{ij}^t + W_{ij}(t, \Delta),$$

¹⁵ The way mergers are handled here (see the Appendix) may help to produce an inverse relationship between a firm's size and its probability of death. But this alone cannot account for this result. Such a relationship has often been noted before. E.g., see [1] [23].

where $V_{ij}(t, \Delta)$ is the mean of $\ln U_{ij}(t, \Delta)$ and $W_{ij}(t, \Delta)$ is a homoscedastic random variable with zero mean. Thus, if $\ln S_{ij}^{t+\Delta}$ is plotted against $\ln S_{ij}^t$, the data should be scattered with constant variance about a line with slope of one. Table 2 contains the least-squares estimate of the slope of each of these lines. In half of the cases where the law was rejected the slope is significantly less than one.

In addition, the variance of $S_{ij}^{t+\Delta}/S_{ij}^t$ tends to be inversely related to S_{ij}^t . Taking in each case a group of small firms and dividing the variance of their values of $S_{ij}^{t+\Delta}/S_{ij}^t$ by the variance among a group of large firms, we obtain the results shown in Table 2. In eight of the ten cases the variances differed significantly. Thus, contrary to this version of the law smaller firms often tend to have higher and more variable growth rates than larger firms.¹⁶

Third, one can postulate that the law holds only for firms exceeding the minimum efficient size in the industry—the size (assuming the long-run average cost curve is J-shaped) below which unit costs rise sharply and above which they vary only slightly. This is the version put forth by Simon and Bonini [27], although it seems to be a stronger assumption than they require.¹⁷ One is faced once again with the problem of whether or not to include firms that die. We excluded them, but the major results would almost certainly have been the same if they had been included.

This version was tested in two ways. First, we estimated the slope of the regression of $\ln S_{ij}^{t+\Delta}$ on $\ln S_{ij}^t$, but included only those firms that were larger than Bain's [4] estimate of the minimum efficient size. The results are quite consistent with Gibrat's law (the slopes never differing significantly from one). Second, we used F tests to determine whether the variance of $S_{ij}^{t+\Delta}/S_{ij}^t$ was constant among these firms. Contrary to

¹⁶ These results differ in part from those of [13] [27] [11] [15]. The latter conclude that there was no tendency for the smaller firms to grow more rapidly than the large ones. But this was due to the fact that they included only very large firms. With regard to the larger variation in growth rates among smaller firms, our findings agree with those in [11] [15], but differ from those in [27]. There is no treatment of this in [13].

All firms that survived during the period are included in these regressions. Note that all crude capacity—domestic and foreign—is included for each firm in the petroleum industry. The data on foreign capacity had to be obtained from the individual firms.

In one case in steel, the slope is significantly less than one but this does not show up in the χ^2 test—largely because of the incomplete coverage in the latter. See the Appendix. One-tailed F tests are used to determine whether the variances differ. In several cases, the variances differ significantly, but it does not show up in the χ^2 tests.

¹⁷ Herbert Simon informs me that the version of Gibrat's law they used in [27] is not required to obtain the Yule distribution and that their proof will hold if the expected value of $S_{ij}^{t+\Delta}/S_{ij}^t$ does not vary with S_{ij}^t , regardless of whether or not the variance of $S_{ij}^{t+\Delta}/S_{ij}^t$ depends on S_{ij}^t . Our results do not contradict these weaker assumptions for firms above the minimum efficient size and consequently they do not contradict their findings based on them. But they do contradict the version of Gibrat's law in [27].

Gibrat's law, the variance of $S_{ij}^{t+\Delta}/S_{ij}^t$ tends to be inversely related to S_{ij}^t in six of the ten cases.¹⁸

Thus, regardless of which version one chooses, Gibrat's law fails to hold in more than one-half of these cases. What sort of mechanism produced the observed departures from this law? The reasons for the inverse relationships between a firm's chance of death and its initial size seem fairly obvious, but why should the data for the survivors show that the smaller firms tend to have higher and more variable growth rates than the larger ones?¹⁹

One very simple model that might help to account for this is as follows. Consider the distribution of growth rates of firms of size S_{ij}^t that would have resulted if none had left the industry. It is not unreasonable to suppose that above some minimum value of S_{ij}^t the average of this distribution would have been about the same in each size class and that it would have exceeded the average growth rate that would have been experienced by firms that left the industry. For simplicity, we assume that the difference between these averages was the same in each size class. Moreover, because each large firm can be viewed as a collection of somewhat independent smaller firms, the variance of this distribution would be expected to be inversely related to S_{ij}^t .²⁰

Then, under the fairly reasonable assumption that the actual growth rate of each survivor is proportional to what it would have been if all

¹⁸ The χ^2 tests had to be abandoned here because of the small number of firms. Firms with more than 64,000 barrels of capacity (petroleum), 1,000,000 net tons of capacity (steel), or .8 per cent of total employment (tires) were included in the regression. The number included in each case is shown in Table 2. The fact that none of the slopes differs significantly from one indicates that there is no evidence that among these firms the average growth rate depended on a firm's initial size.

In the variance ratio tests we divided these firms into two size (S_{ij}^t) groups, the dividing line being 150,000 barrels of capacity (petroleum), 3,000,000 tons of capacity (steel), and 30,000 employment (tires). Then F tests were used to determine whether the variances of $S_{ij}^{t+\Delta}/S_{ij}^t$ differed. This test is not too robust with regard to departures from normality, but it should perform reasonably well here.

Note that in petroleum and tires we include firms that are more than one-half of the minimum efficient sizes given in the Appendix. According to Bain [4], the cost curve is quite flat back to one-half of those sizes. Thus, it seemed acceptable to include the additional firms and to increase the power of the tests in this way.

¹⁹ Note that the inverse relationship between S_{ij}^t and the average growth rate shows up only when all firms are included. There is no evidence of this among firms exceeding the minimum efficient size. (The inverse relationship between S_{ij}^t and the variability of growth rates shows up in both cases.)

²⁰ The growth rate of a large firm can be viewed as the mean of the growth rates of its smaller "components" (e.g. plants). This point has also been made in [15]. Note that, if the growth rates of the components (plants or otherwise) were independent, the standard deviation would be inversely proportional to the square-root of a firm's size. But, since they tend to be located in the same region and have other similarities, one would expect the growth rate of such components to be positively correlated. Thus, the standard deviation would not be expected to decrease as rapidly with increases in size as the square-root formula suggests. In fact, this expectation turns out to be true.

firms had survived, one can show that

$$\sigma_S^2(S) = \mu^2 \left\{ \sigma_t^2(S) - \frac{P(S)K^2}{[1 - P(S)]^2} \right\},$$

where $\sigma_S^2(S)$ is the variance of the growth rates of the survivors (originally of sizes S_{ij}^t), $\sigma_t^2(S)$ is the variance of the growth rates of all firms (originally of size S_{ij}^t) that would have resulted if all had survived, K is the difference between the average growth rate of all firms (if none had left) and the average growth rate that would have been experienced by those leaving the industry, $P(S)$ is the probability of death for firms initially of size S_{ij}^t and μ is the ratio of a survivor's actual growth rate to what it would have been if all had survived. (This assumes that if they had not left, the firms originally of size S_{ij}^t that left the industry would have had growth rates with a variance of $\sigma_t^2(S)$.)

In addition, one can show that the average growth rate of the survivors originally of size S_{ij}^t equals

$$\bar{S}(S) = \mu \left\{ \bar{l} + \frac{P(S)K}{1 - P(S)} \right\},$$

where \bar{l} is the average growth rate for all firms of size S_{ij}^t if none had left the industry. Note that we, in the same spirit as [27], are stipulating only that \bar{l} will be constant above some minimum size.

Thus, if $\sigma_t^2(S)$ is inversely related to S_{ij}^t (for the reason discussed in note 20) and if $P(S)$ is inversely related to S (which certainly is true), it follows that $\sigma_S^2(S)$ will be inversely related to S_{ij}^t so long as $P(S) > 1/3$ or $d\sigma_t^2(S)/dS_{ij}^t$ is large in absolute terms relative to $dP(S)/dS_{ij}^t$. Moreover, it follows that $\bar{S}(S)$ will be inversely related to S_{ij}^t .

Thus, if this highly simplified model should be at all reliable, one would often expect to observe departures from Gibrat's law of the sort found in Table 2. Research should be carried out to develop and study more sophisticated models of the growth process. Although Gibrat's law is very convenient from an analytical point of view, it does not seem to hold up very well empirically. It seems to be a rather unreliable base on which to rest theories of the size distribution of firms.

B. *Successful Innovation and the Growth of Firms*

How much of an impact does a successful innovation have on a firm's growth rate? In another study [17], I presented a list of the firms that were first to introduce the significant new processes and products that emerged since the First World War in the steel and petroleum refining industries. (See the Appendix for a brief description of this list.) A comparison of their growth rates—during the period in which the innovation occurred—with those of other comparable firms should help to indicate

how great the pay-off is (in terms of growth) for a successful innovation.

For each period for which we have data, Table 3 estimates the average annual growth rate of (1) firms that carried out significant innovations during the period, and (2) other firms that were equal in size to the successful innovators at the beginning of the period. There is a marked difference between the two groups. In every time interval and in both industries, the successful innovators grew more rapidly than the others; and in some cases, their average rate of growth was more than twice that of the others.²¹

Taking each innovator separately, the difference between its growth rate and the average growth rate of other comparable firms seems to have been inversely related to its size. As one would expect, a successful innovation had a much greater impact on a small firm's growth rate than on a large firm's. The fact that fewer of the successful innovators in more recent periods were small firms probably accounts in part for the decrease over time in the average difference (in Table 3) between the two groups.²²

Each growth rate in Table 3 pertains to the entire period indicated in the caption—whereas the innovations occurred sometime within the period. Consider the period from time t to time $t+\Delta$. Suppose that the j th successful innovator in this period introduced its innovation at time t_j , that its average annual growth rate from time t to time t_j exceeded that of other comparable firms by e_j , and that its average annual growth rate from time t_j to time $t+\Delta$ exceeded that of other comparable firms by e_j+d_j . What were the average values of e_j and d_j ? If the innovators grew more rapidly than other firms because of certain characteristics associated with the innovation, but not because of the innovation itself, and if these characteristics had approximately the same effect throughout the period, the average value of d_j would be expected to be zero.

²¹ Note: (1) We are not comparing innovators with noninnovators, since some of the "other firms" may have been unsuccessful innovators. Because we can only include successful innovators (the data being what they are), it is not surprising that they have higher growth rates, and we are much more interested in the size of the difference than in its existence. (2) Some of the innovators introduced more than one innovation during the period. Thus, the difference in growth rates is not due entirely to a single innovation. But in the subsequent analysis (involving \bar{d}) only cases involving a single innovation are included. (3) It would be interesting to see how an innovation's effects depended on its character, but we have too little data to attempt this. (4) The way in which the average annual growth rate of the "other firms" in Table 3 was computed is described in the Appendix.

²² If the innovators in steel are divided into two groups—those above 1,000,000 tons and those less than (or equal to) 1,000,000 tons at the beginning of the period—the average difference between their growth rates and the growth rates of other comparable firms differs considerably between the groups. Among the larger firms, the average difference is generally about .5 points whereas it is 3–10 points among the smaller ones. Similarly, if the innovators in petroleum are divided into two groups—those above 32,000 barrels and those less than (or equal to) 32,000 barrels at the beginning of the period—the average difference is practically zero among the larger firms but 6–24 points among the smaller ones.

TABLE 3—AVERAGE ANNUAL GROWTH RATES OF SUCCESSFUL INNOVATORS AND OTHER FIRMS (OF COMPARABLE INITIAL SIZE), COMPUTED VALUES OF \bar{e} AND \bar{d} , AND REGRESSIONS (EXCLUDING INNOVATORS) OF $\ln S_{ij}^{t+\Delta}$ ON $\ln S_{ij}^t$, STEEL AND PETROLEUM REFINING INDUSTRIES, SELECTED PERIODS.^a

Item	Steel				Petroleum

^a Symbols: S_{ij}^t is the size of the j th firm in the i th industry at time t ; $S_{ij}^{t+\Delta}$ is its size at time $t+\Delta$; \bar{e} is the average value of e_j , where e_j is the difference between the average annual growth rate of the j th innovator during the period from time t to time t_j and that of "other firms" of equivalent size (at time t) during the same period; and \bar{d} is the average value of d_j , where e_j+d_j is the difference between the average annual growth rate of the j th innovator during the period from time t_j to time $t+\Delta$ and that of "other firms" of equivalent size (at time t) during the same period. See the Appendix for the way in which the regressions described here are used to estimate the figures in the second row of this table.

^b No figures are computed in cases where there were only a few innovators. See note 23 and the Appendix for a discussion of the derivation of these figures.

Source: See the Appendix and Mansfield [17].

Letting $S_j^{t+\Delta}$ be the size (i.e., capacity) at time $t+\Delta$ of the j th innovator and $Q_j^{t+\Delta}$ be the average logarithm of the sizes at time $t+\Delta$ of the other firms that were equal in size to the j th innovator at time t , one can show that

$$(11) \quad (\ln S_j^{t+\Delta} - Q_j^{t+\Delta})/\Delta = e_j + [1 - (t_j - t)/\Delta]d_j.$$

To see this, consider the k th "other firm" of the same size as the j th innovator at time t . If r_{1k} is its average rate of growth between time t and time $t+j$, r_{2k} is its average rate of growth between time t_j and time $t+\Delta$, and $S_{jk}^{t+\Delta}$ is its size at time $t+\Delta$,

$$\ln S_{jk}^{t+\Delta} = \ln S_j^t + r_{1k}(t_j - t) + r_{2k}(t + \Delta - t_j).$$

Thus, if r_1 is the average value of r_{1k} and r_2 is the average value of r_{2k} ,

$$Q_j^{t+\Delta} = \ln S_j^t + r_1(t_j - t) + r_2(t + \Delta - t_j).$$

But by the definitions of e_j and d_j ,

$$\ln S_j^{t+\Delta} = \ln S_j^t + (r_1 + e_j)(t_j - t) + (r_2 + e_j + d_j)(t + \Delta - t_j).$$

Thus,

$$\ln S_j^{t+\Delta} - Q_j^{t+\Delta} = e_j\Delta + d_j(t + \Delta - t_j),$$

and equation (11) follows.

Letting \bar{e} and \bar{d} be the average values of e_j and d_j and assuming that $(e_j - \bar{e})$ and $(d_j - \bar{d})$ are statistically independent of $(t_j - t)/\Delta$, we have

$$(12) \quad (\ln S_j^{t+\Delta} - Q_j^{t+\Delta})/\Delta = \bar{e} + [1 - (t_j - t)/\Delta]\bar{d} + W_j,$$

where W_j can be treated as a random error term. Using equation (12) we can apply least-squares to obtain \bar{e} and \bar{d} .²³

The results (in Table 3) indicate that \bar{d} was always positive, but that the sign of \bar{e} varied. This means two things. First, in the period immediately before they introduced the innovations, there was no persistent tendency for the successful innovators to grow more rapidly than other comparable firms. In some cases they grew more rapidly, but in others they did not. Thus, their higher growth rate cannot be attributed to their preinnovation behavior. Second, in the period after they introduced the innovations their mean growth rate consistently exceeded that of other comparable firms by more than it had before their introduction—which is what one would expect.

If one makes the crude assumption that the pre-innovation difference in average growth rate between successful innovators and other firms would have been maintained from time t to time $t + \Delta$ if the innovations had not been introduced, \bar{d} measures the average effect of these successful innovations on a firm's growth rate during the relevant period. Based on this assumption, their average effect was to raise a firm's growth rate by 4–13 percentage points, depending on the particular time interval and industry. In view of the widespread interest in measures of the pay-

²³ To estimate $Q_j^{t+\Delta}$, we use the procedure described in the Appendix. In computing \bar{e} and \bar{d} , innovators that introduced more than one innovation had to be excluded (except in a few cases where the innovations were all introduced at the same time). These relatively few omissions are ignored, and we act as if we had the entire population of innovators in the analysis.

Of course, the assumption that $(e_j - \bar{e})$ and $(d_j - \bar{d})$ are statistically independent of $(t_j - t)/\Delta$ is rather bold. Some bias may result if d_j is higher immediately after the introduction of an innovation. If so $(d_j - \bar{d})$ and $1 - (t_j - t)/\Delta$ may be negatively correlated, and we would probably overestimate \bar{e} and underestimate \bar{d} .

Where there were only a few innovators, this assumption (and the one in the previous paragraph) seemed particularly risky and we did not compute values of \bar{e} and \bar{d} . But some preliminary work suggested that, had we done so, the results would have been much the same.

off from successful innovation, these estimates, despite their crudeness, should be useful. Of course, estimates of the effects of successful innovation on a firm's profits would be even more useful, but they lie outside the scope of this paper.²⁴

III. *Mobility within an Industry's Size Structure*

In recent years, economists have become quite interested in the amount of mobility in an industry—i.e., the extent to which firms change their relative positions in the size distribution. The importance of this characteristic of an industry has been pointed out by Adelman [1], Hart and Prais [13], Simon and Bonini [27], and others [22] [28]. This section measures the amount of mobility in several industries and constructs a simple model to help explain its observed variation. The results shed additional light on the process of firm growth, since the amount of mobility is obviously related to the amount of interfirm variation in growth rates.²⁵

To measure the amount of mobility in the i th industry during the t th period, suppose that we have a list of all firms that were in existence at both the beginning and end of the period. Suppose that a firm is chosen at random from this list. Then suppose that another firm is chosen at random from those that were 60–70 per cent as large as the first firm at the beginning of the period. The probability that the second (initially smaller) firm will be bigger than the first (initially larger) firm at the end of the period is a rough measure of the amount of mobility. Let this probability be P_{it} .²⁶

²⁴ Note that the successful innovators tend to be the large spenders on research. (For evidence on this score and discussions of the imitation process, see [16] [18] [19] [20].)

If we had complete, year-by-year data on each firm's size, we could compute \bar{e} and \bar{d} without making the assumption discussed in note 23. The differences in growth rates shown in Table 3 are averages over periods of 1–10 years after an innovation was introduced. Obviously, the effects of an innovation decrease as time goes on.

Finally, for the reason cited in note 23, the estimates of \bar{d} may be biased downward. On the other hand, in the petroleum industry in 1947–57, \bar{d} may be unduly affected by one firm and is probably too high. Note, too, that the observed differences in growth rate may still be due in part to other factors that are associated with a firm's willingness to innovate and the timing of the innovation.

²⁵ If Gibrat's law held and if $W_{ij}(t, \Delta)$ were normally distributed, the amount of mobility would be solely a function of the latter's variance. For this reason, its variance has sometimes been suggested as a measure of the amount of mobility. But, since Gibrat's law generally does not hold and then normal distribution is only an approximation, the measure discussed below seems preferable.

²⁶ The choice of 60–70 per cent is arbitrary. We could have experimented with alternative ranges, but the amount of clerical work involved would have been prohibitive. Note that this measure is based on all firms; if one were interested in the amount of mobility among the larger firms only, the measure could easily be modified to that end.

This measure is based solely on firms that survived until the end of the period. If we included all firms—regardless of whether or not they survived—the results would depend heavily on the death rate. Because the latter was already taken up in Section I, it seemed preferable to use

Table 1 contains estimates of P_{it} for various periods in the history of the steel, petroleum refining, and rubber tire industries. Because of the small number of firms, it was impossible to obtain meaningful estimates for the automobile industry. To help explain the considerable variation in P_{it} , we assume that

$$(13) \quad P_{it}(S) = h(S/(n_{it}\bar{S}_{it}), A_{it}, S_{it}^*/\bar{S}_{it}, n_{it}, \dots),$$

where $P_{it}(S)$ is the probability that a firm of size S at the beginning of the period will be smaller at the end of the period than a firm originally of size $.6S-.7S$, n_{it} is the number of firms in the industry at the beginning of the period, \bar{S}_{it} is their mean size, \bar{S}_{it} is their median size, S_{it}^* is the size of firm such that firms exceeding it accounted for one-half of the market, and A_{it} is the age of the industry.

What are the effects of these variables? First, the smaller firm's chance of overtaking the larger one will be inversely related to the initial difference between their market shares—which is proportional to $S/(n_{it}\bar{S}_{it})$. Second, as an industry grows older, stronger ties are established between firms and their customers, the technology becomes more settled, and the industry's structure tends to become more rigid. Thus, A_{it} —which is a proxy variable for these factors—is likely to be important.²⁷ Third, $P_{it}(S)$ is likely to be inversely related to the amount of concentration in the industry. Thus, n_{it} and S_{it}^*/\bar{S}_{it} (a convenient measure of the amount of inequality among firm sizes) are included.²⁸

this measure. If one is interested in results that include deaths, it is relatively easy to combine the findings in this Section with those in Section I.

Let $P_{it}'(S)$ be the probability that a firm initially of size S will be smaller at the end of the period than—or as small as—a firm that initially was 60–70 per cent of its size. If a firm dies, let its size be zero. Then

$$P_{it}'(S) = R_{it}(S) + [1 - R_{it}(S)][1 - R_{it}(S')]P_{it}(S),$$

where $R_{it}(S')$ is the probability that a firm of initial size, $.6S-.7S$, will die during the period. Since Section I B takes up $R_{it}(S)$ —and $R_{it}(S')$ —and this section analyzes $P_{it}(S)$, together they provide information regarding $P_{it}'(S)$.

²⁷ The age of an industry is a somewhat slippery concept. In 1896, Goodyear made the first U.S. tires for commercial vehicles. In 1859, oil production began in the United States. The production of iron began here in 1645. Using these years as estimates of the dates of birth of the industries, A_{it} was derived by subtracting them from the initial year of the i th period. Although the results seem reasonable, their crudeness should be obvious.

²⁸ Since we assume that the distribution of firms by size is log-normal, the obvious measure of their inequality is the variance of the logarithms of the firm sizes. It can be shown that the latter is equal to $\ln(S_{it}^*/\bar{S}_{it})$. Thus, our measure—which is convenient because it allows some terms in equation (15) to be collected—is a monotonic increasing function of the variance.

The chief reason for using a measure of inequality of firm sizes plus the number of firms as a measure of concentration is convenience. For some disadvantages in the use of such measures, see [2]. For some evidence that increases in concentration are associated with decreases in mobility, see [15]. Of course, one would expect this variable to be important because where markets are highly concentrated it is more likely that discipline can and will be maintained to see to it that firms remain in about the same relative positions. E.g., there may be explicit or tacit agreements to share markets, each firm maintaining a certain per cent of the total.

Since the effects of these variables are likely to be multiplicative, we assume that

$$(14) \quad P_{it}(S) = \beta_0 [S / (n_{it} \bar{S}_{it})]^{-\beta_1} A_{it}^{-\beta_2} (S_{it}^* / \bar{S}_{it})^{-\beta_3} n_{it}^{\beta_4} Z_{it}''$$

where Z_{it}'' is a random error term and the β 's are presumed to be positive. Assuming again that the distribution of firms by size is log-normal, we have:

$$\begin{aligned} P_{it} &= \int_0^\infty P_{it}(S) \rho_{it}(S) dS \\ &= \beta_0 \left[\int_0^\infty S^{-\beta_1} \rho_{it}(S) dS \right] \bar{S}_{it}^{\beta_1} A_{it}^{-\beta_2} (S_{it}^* / \bar{S}_{it})^{-\beta_3} n_{it}^{\beta_4 + \beta_1} Z_{it}'' \\ (15) \quad P_{it} &= \beta_0 (1 + V_{it}^2)^{\beta_1(1+\beta_1)/2 - \beta_3} A_{it}^{-\beta_2} n_{it}^{\beta_4 + \beta_1} Z_{it}'' \end{aligned}$$

To see how well this model can represent the data, we take logarithms of both sides of equation (15), and using the data in Table 1, we obtain least-squares estimates of the coefficients. The results are:

$$(16) \quad \ln P_{it} = - .55 - .57 \ln (1 + V_{it}^2) - .15 \ln A_{it} + .29 \ln n_{it},$$

(.20)
(.07)
(.08)

where the quantities in parentheses are standard errors and $\ln Z_{it}''$ is omitted. Figure 2 shows that equation (16) can explain much of the variation in $\ln P_{it}$, the coefficient of correlation (corrected for degrees of freedom) being about .90. All of the regression coefficients have the expected signs and are statistically significant at the .05 level. Thus, what evidence we have seems to be quite consistent with the model. Indeed, it fits the data surprisingly well.²⁹

IV. Concluding Remarks

A. Limitations

Some of the limitations of this study are the following: First, the empirical results in Sections I and III are based on relatively few ob-

²⁹ The expression in equation (15) is not a very obvious one. E.g., it is not obvious (at least to me) that $\ln P_{it}$ should be a linear function of $\ln (1 + V_{it}^2)$. Consequently, it is all the more satisfying that this function turns out to be such a good representation of the data.

There is some evidence that the variability of firm growth rates increases with the industry's over-all rate of growth [15]. Of course, A_{it} and the industry's growth rate are liable to be related in general. But in the cases used here, there is no correlation between the two variables. Consequently, the observed effects of A_{it} are not mere reflections of the effects of the industry's growth rate.

Another factor that may be important is the extent to which the smaller firms tend to be the innovators. In addition, Hart and Prais [13] provide some evidence that there is more mobility during depressions, but this may be due to the differences among industries in the extent to which sales fall during a recession. Our data—which do not lump all industries together—do not show any obvious signs of such a tendency.

In deriving equation (15), we presume that $P_{it}(S)$ exists for all S . But in some cases there are no firms 60–70 per cent as large as another firm. Thus, strictly speaking, we should use the size distribution of firms where it exists.

FIGURE 2. PLOT OF ACTUAL VALUES OF P_{it} AGAINST THOSE COMPUTED FROM EQUATION (16), STEEL, PETROLEUM, AND RUBBER TIRE INDUSTRIES, SELECTED PERIODS.

Source: Table 1 and equation (16). P_{it} is the probability that a randomly drawn firm in the i th industry will be smaller at the end of the t th period than another firm drawn randomly from those 60-70 per cent of its size at the beginning of the t th period.

servations. Considerable work was required to obtain even this small number because each observation is based on a large amount of relatively inaccessible data. But regardless of the reasons, the small number of industries and time periods results in fairly substantial sampling errors and obvious dangers of bias.

Second, the basic data in Table 1 are often very rough. The estimates of E_{it} , R_{it} , C_{it} , Π_{it} , A_{it} , and $\bar{S}_{it}/\hat{S}_{it}$ are based on the rather crude assumptions described in the Appendix. Unfortunately, no better data could be found. To the extent that they are distributed randomly, the

errors of measurement in the exogenous variables tend to bias the estimates of the coefficients in equations (3), (7), and (16) toward zero.

Third, the models in Sections I and III are obviously oversimplified. The small number of observations, as well as measurement problems and lack of data, limited the number of explanatory variables that could be included. One other explanatory variable—the length of the time period—was used initially in equations (3), (7), and (16), and its effect turned out to be nonsignificant.³⁰ Note too that the residuals in these equations may not be entirely independent because of the effects of factors that persist in a given industry or time period.

Fourth, the estimating procedures are sometimes rough. In Section II, the computed values of \bar{e} and \bar{d} are based on a rather bold assumption. In Section I, there is probably some least-squares bias toward zero in the estimates of the α 's and ν 's because Π_{it} is inversely related to E_{it} and directly related to R_{it} . But in the case of α_2 and ν_2 , this bias should not be very large, and considering the quality of the basic data, it did not seem worthwhile to use more complicated estimating procedures.³¹

B. *Summary and Conclusions*

Despite their limitations, the results contribute in at least four ways to a better understanding of the processes of firm formation, growth, and decline. First, they help to gauge the effects of an industry's profitability, capital requirements, and minimum efficient size of firm on its rates of entry and exit. For example, they suggest that the entry rate would increase by at least 60 per cent if an industry's profitability doubled and that it would decrease by at least 7 per cent if its capital requirements doubled. Similarly, they suggest that the exit rate would decrease by at least 15 per cent if an industry's profitability doubled or if the ratio of the average size of firm to the minimum efficient size of firm doubled.

³⁰ Of course, the exclusion of important factors can create biases of various sorts. E.g., it is possible that C_{it} is correlated with other barriers to entry and that consequently its effects on E_{it} are overstated.

³¹ For an elementary discussion of least-squares bias of this sort, see [5]. To evaluate the bias, we first formed a complete system of equations by adding to equations (3) and (7) a third equation in which $\ln \Pi_{it}$ is represented as a linear function of $\ln E_{it}$, $\ln R_{it}$, $\ln \Pi_{it(t-1)}$, an unspecified exogenous variable, and an error term. As noted in the text, the coefficient of $\ln E_{it}$ in the third equation is assumed to be negative and the coefficient of $\ln R_{it}$ is assumed to be positive. What we have in mind is that the rate of change of Π_{it} (i.e., $\Pi_{it}/\Pi_{it(t-1)}$) is an increasing function of R_{it} , a decreasing function of E_{it} , and a function of some other (unspecified) exogenous variable. Next, we assumed that the residuals in the equations were uncorrelated (which is consistent with the data we have), and we assumed for simplicity that the covariances of the exogenous variables were all zero.

Under these conditions we found that the asymptotic bias in the estimates of the α 's and ν 's was always towards zero and that it was likely to be a small percentage of the estimates of α_2 and ν_2 . But this only holds in the limit and our assumptions are obviously rough.

Second, the tests of several variants of Gibrat's law of proportionate effect reveal that, contrary to the law, smaller firms have relatively high death rates and those that survive tend to have higher and more variable growth rates than larger firms. Moreover, a simple theory is presented which may help to account for these deviations from the law of proportionate effect.

Third, evidence as to the effects of successful innovations on a firm's rate of growth indicate that on the average the successful innovators in these industries grew about twice as rapidly as other comparable firms during the relevant period.³² In terms of short-term growth, the rewards for successful innovation seem to have been substantial, particularly for smaller firms.

Fourth, a simple model is presented to help explain variation among industries and over time in the extent to which firms change their relative positions in the size distribution of an industry. Our tentative findings indicate that the amount of mobility in an industry depends significantly on its age and its market structure, the model fitting data for several industries surprisingly well.

In recent years, economists have begun to study in a systematic way the changes over time in an industry's composition and structure, but because so little econometric work has been carried out, they have had relatively little to go on in constructing models to represent the relevant dynamic processes. For this reason and others, they have not proceeded far beyond the simplest sorts of stochastic models, e.g., Markov processes with constant transition probabilities based on Gibrat's law.³³ By providing some of the necessary econometric results, this paper should contribute to the development of a richer theory of the dynamic aspects of industrial structure.

APPENDIX: DATA AND METHODS

First, this Appendix presents the basic data regarding the birth, growth, and death of firms in the steel, petroleum refining, and rubber tire industries. (The data for the automobile industry pertain to only a small number of firms and are readily available in the annual statistical issues of *Automobile Industries*.) These data can be summarized most easily in the form of transition matrices—shown in Tables A, B, and C. If all firms are classified into n size classes, the ij th element of the transition matrix for a particular period ($i, j = 1, \dots, n$) is the number of firms in the i th class at the beginning of the period that were in the j th class at the end. Despite the pioneering work of Hart and Prais [13] and Adelman [1], few such transition matrices have been constructed.

³² The average growth rate in the first row of Table 3 is approximately double the average growth rate in the second row.

³³ Judging by our results and the transition matrices in the Appendix, the assumption—sometimes made—that the transition probabilities are constant over time is likely to be a poor one; e.g., the extent of “mixing” [27] seems to decrease with time.

Table A contains transition matrices for the steel industry for 1916-26, 1926-35, 1935-45, and 1945-54; Table B, for petroleum refining for 1921-27, 1927-37, 1937-47, and 1947-57; Table C, for the rubber tire industry for 1937-45 and 1945-52. Some of these periods were dictated by the availability of data; others were chosen rather arbitrarily. A firm's size is measured in terms of gross tons of ingot capacity (steel), daily crude capacity (petroleum), or employment (tires). In steel and petroleum, all firms with ingot capacity or crude capacity are included. In rubber tires, all firms cited in the *Rubber Red Book* as manufacturers of rubber tires are included.

The basic data were derived from the *Directory of the American Iron and Steel Institute* [3] Bureau of Mines bulletins [6], the *Petroleum Refiner*, the *Rubber Red Book*, *Moody's Industrials*, and correspondence with particular firms. To construct each matrix, we obtained from these sources complete lists of the firms in the industry at the beginning and end of the period and

^a See note a, Table A. Both domestic and foreign capacity owned by firms are included.

the size of each firm at both points in time. With this information at hand, it was a simple matter to construct each matrix.

Four points should be noted regarding these data: (1) When a firm's name appeared on a list for the first time, we assumed that it entered the industry during the preceding period. Similarly a firm is regarded as having left the industry when its name disappeared from the lists. Although we tried to keep track of mere changes in company names (where changes in ownership were not involved), some were undoubtedly missed and hence the entry and exit rates may be inflated. But on the other hand, they may also be underestimated because some firms may have kept the same names despite a change in ownership. (Of course, for large corporations, changes in ownership occur to some extent all the time and are not very important unless changes in the control of the firm are involved.) Unfortunately, the available data force us to use a firm's name as an indicator of its ownership. But one would certainly expect the resulting rates of entry and exit to be closely related to the actual ones. Of course, if they are proportional on the average, there is no problem. But this is unlikely.

(2) When mergers occurred, they were treated as if the largest firm involved in the merger bought the others. That is, the resulting firm was regarded as a continuation of the largest of its components, and the other parties to the merger were treated as if they went out of business. This procedure is arbitrary, but no other seems clearly preferable. Fortunately, it should not affect the results very substantially. Note too that some of the entrants may have "purchased" existing facilities by merging with established firms. (3) Some members of the industry did not provide data regarding their size at some of these points in time, and there was no choice but to omit them during the relevant periods. This should be of little consequence because only a few such cases were encountered. Note that this accounts for the fact that the number entering a particular size class sometimes differs from the number in that size class at the beginning of the next period. (4) The steel data pertain to all firms with ingot capacity (open hearth, bessemer, or electric) and the petroleum data pertain to all firms with crude capacity (operating or shut-down). For some purposes, it might have been preferable to have excluded electric furnaces and shut-down capacity.

Second, we describe the way in which the data in Table 1 regarding Π_{it} , C_{it} , V_{it} ,² and $\bar{S}_{it}/\hat{S}_{it}$ were derived. To estimate Π_{it} , we needed figures on profits after taxes as a percentage of net worth in each industry. For rubber tires, the data came from the *Statistics of Income*. For petroleum, they came from Epstein [10], De Chazeau and Kahn [9], and the *Statistics of Income*. For steel, they came from Schroeder [26], but some adjustment was made for differences in concept. The data for automobiles came from *Moody's* and pertained to the largest five firms. The 1925-57 data for all manufacturing came from the First National City Bank of N.Y. (as reported in the 1959

^a See note a, Table A. In each year a few firms had to be excluded because the *Rubber Red Book* provided no employment figures for them.

Petroleum Facts and Figures). The earlier data for all manufacturing came from Epstein [10].

In many respects, the data are rough. An unweighted average of the profit rates of firms above the minimum efficient size would seem appropriate here. But judging by Bain's figures [4], there is little correlation between size and profit rate in steel, petroleum, and tires; and firms above the minimum efficient size account for almost all of the assets. Thus the weighted averages that we use should be fairly good approximations. In autos, there seems to be some correlation of this sort and consequently we use an unweighted average. This results in a much lower figure for autos than the weighted average that is generally published. For 1949-59, the figure seems much too low, but it could be appreciably higher without affecting the results substantially.

To obtain C_{it} in each industry, we multiplied Bain's estimate [4] of the required investment by the ratio of the average size of firm at the beginning of the i th period (measured in terms of capacity in steel and petroleum, production in automobiles, and employment in tires) to the average size of firm in 1945 (steel), 1947 (petroleum), 1949 (autos), or 1945 (tires). (By Bain's estimate we mean the average of the upper and lower limit he gives. It includes initial losses in the case of the automobile industry.) If the ratio of the average size to the minimum efficient size of firm remained constant over time in each industry and if the necessary investment varied in proportion to the minimum efficient size, this would be all right. This is probably as sensible as any of the simple, operational assumptions we could make, but its crudeness is obvious.

Note that C_{it} —even if it were accurately measured—would not necessarily be the minimum investment for an entrant because the typical entrant was below the minimum efficient size. For the same reason, the typical entrant could not expect to earn profits of Π_{it} . But it seems reasonable that the expected profitability of the typical entrant would be closely related to Π_{it} . And since the average size of an entrant is a relatively constant proportion of the minimum efficient size in these cases, it is pretty certain that the average capital requirements would be closely related to C_{it} .

The estimates of V_{it} ² were obtained from the frequency distributions in Tables A-C and from *Moody's* figures on assets of automobile firms. To estimate the ratio of the average size of firm to the minimum efficient size, we divided Bain's estimate [4] of the minimum efficient size in each industry into the average size of firm in 1947 (petroleum), 1945 (steel and tires), or 1949 (autos). The estimates of the minimum efficient size were 1,000,000 net tons of capacity (steel), 120,000 barrels of capacity (petroleum), 1½ per cent of total employment (tires), and 10 per cent of total production (autos). The average size of firm in each case came from Tables A-C and *Automotive Industries*. Then we assumed that this ratio was constant over time. Note that the minimum efficient size for the production of specialty items (and in certain locations) may be less than this. This may be quite important. For further comments, see note 18. The crudeness of these estimates of $\bar{S}_{it}/\hat{S}_{it}$ is obvious.

Third, we describe the way in which firms were classified by S_{it} and $S_{it}^{t+\Delta}/S_{it}$ in the χ^2 tests in Table 2. In the tests where deaths were included, the following size classes were used. In steel, we classified firms by their value of S_{it} into four classes: 4,000–15,999 tons, 16,000–63,999 tons, 64,000–255,999 tons, and 256,000–4,096,000 tons. In tires, we used four classes: 20–79 men, 80–159 men, 160–639 men, and 640–5,119 men. And in petroleum, there were four classes: 500–999 barrels, 2,000–3,999 barrels, 8,000–15,999 barrels, and 32,000–511,999 barrels. To cut down the computations involved, only firms in these classes were included. Thus, some of the largest and smallest firms were omitted in steel and tires, and some small, medium-sized, and large firms were excluded in petroleum. But had all firms been included, the results would almost certainly have been much the same.

In all cases, the firms in a size class were divided into three groups—those where $S_{it}^{t+\Delta}/S_{it}$ was less than .50, between .50 and 1.50, and 1.50 or more. These classes were chosen so that the expected number of firms in each cell of the contingency table would be five or more. (According to a well-known rule of thumb, the expected number in each cell should be this large.) This did not always turn out to be the case, but further work showed that the results would stand up if cells were combined.

With the following exceptions, these same classifications were used in the tests where deaths were excluded. In steel and tires, the two smallest size classes were combined. In some cases, firms were classified into groups where $S_{it}^{t+\Delta}/S_{it}$ was less than 1.00, between 1.00 and 2.00, and 2.00 or more. These changes were made to meet the rule of thumb noted above. Despite these changes, the expected number of firms in some cells was not quite five, but the results would not be affected if some cells were combined.

Fourth, we describe the way in which the innovators in Section II B were identified. The first step was to write trade associations and trade journals in each industry and to ask for a list of the important processes and products first introduced in the industry since 1918. Usable questionnaires were filled out and returned by one trade association and three trade journals. There was evidence that the respondents went to considerable pains in preparing them. The number of innovations of each type (process and product) that were provided ranged from about 20 to 40. In all, about 150 innovations were listed in the replies.

The second step was to determine what firm first introduced each innovation commercially and when this took place. To determine the date and to identify the innovator, articles in trade and technical journals were consulted. When doubts arose, letters were sent to equipment producers and members of the industry to determine whether the information was correct. Members of the Carnegie Institute of Technology engineering faculty were also consulted. Ultimately, the required information was obtained for over 80 per cent of the innovations. These data appear in [17].

Finally, we describe the way in which the average annual growth rate of the "other firms" in Table 3 was computed. If the innovator was smaller than the sizes given in the second sentence in note 18, we used the following

technique to estimate the average annual growth rate of the other firms of its initial size. We assumed that, for the j th "other firm" in the i th industry, $\ln S_{ij}^{t+\Delta} = a_i + b_i \ln S_{ij}^t + Z_{ij}''$, where Z_{ij}'' is a random error term. A equation of this form fits the data for the smaller firms quite well. We then obtained least-squares estimates (shown in Table 3) of a_i and b_i ; and taking each innovator, we used this regression to estimate the average value of $\ln S_{ij}^{t+\Delta}$ for the "other firms" corresponding to its value of S_{ij}^t . Deducting its value of $\ln S_{ij}^t$ from this computed average value and dividing the result by Δ , we obtain an estimate of the average annual growth rate of "other firms" of the same original size as this innovator.

If the innovator was larger than the sizes given in note 18, we had to use another method because the regressions do not always fit the larger firms very well. In these cases, we used the average annual growth rate of the "other firms" larger than the sizes given in note 18. Finally, to obtain the figures in the second row of Table 3, we took the resulting average growth rate for the "other firms" corresponding to each innovator during the period (whether or not it was above the sizes in note 18) and averaged them.

BEHAVIOR OF THE FIRM UNDER REGULATORY CONSTRAINT

By HARVEY AVERCH AND LELAND L. JOHNSON*

In judging the level of prices charged by firms for services subject to public control, government regulatory agencies commonly employ a "fair rate of return" criterion: After the firm subtracts its operating expenses from gross revenues, the remaining net revenue should be just sufficient to compensate the firm for its investment in plant and equipment. If the rate of return, computed as the ratio of net revenue to the value of plant and equipment (the rate base), is judged to be excessive, pressure is brought to bear on the firm to reduce prices. If the rate is considered to be too low, the firm is permitted to increase prices.

The purpose here is (a) to develop a theory of the monopoly firm seeking to maximize profit but subject to such a constraint on its rate of return, and (b) to apply the model to one particular regulated industry—the domestic telephone and telegraph industry. We conclude in the theoretical analysis that a "regulatory bias" operates in the following manner: (1) The firm does not equate marginal rates of factor substitution to the ratio of factor costs; therefore the firm operates inefficiently in the sense that (social) cost is not minimized at the output it selects. (2) The firm has an incentive to expand into other regulated markets, even if it operates at a (long-run) loss in these markets; therefore, it may drive out other firms, or discourage their entry into these other markets, even though the competing firms may be lower-cost producers. Applying the theoretical analysis to the telephone and telegraph industry, we find that the model does raise issues relevant to evaluating market behavior.

I. The Single-Market Model

First we shall consider a geometrical and a mathematical framework showing the effect of the regulatory constraint on the cost curves of the

*The authors, research economists at The RAND Corporation, are indebted to Kenneth Arrow who suggested a mathematical framework when the ideas in this paper were in an early state of development. Any views expressed in this paper are those of the authors. They should not be interpreted as reflecting the views of The RAND Corporation or the official opinion or policy of any of its governmental or private research sponsors. An earlier version of this paper was presented at the Econometric Society meetings on December 28, 1961 in New York.

firm employing two factors. The essential characteristic to be demonstrated is: if the rate of return allowed by the regulatory agency is greater than the cost of capital but is less than the rate of return that would be enjoyed by the firm were it free to maximize profit without regulatory constraint, then the firm will substitute capital for the other factor of production and operate at an output where cost is not minimized.

Figure 1 denotes the firm's production where capital x_1 is plotted on the horizontal axis and labor x_2 on the vertical axis. The market or

FIGURE 1

"social" cost of capital and labor generates the isocost curve *A* and the *unregulated* firm would move along expansion path 1 where market cost is minimized for any given output. With regulation, however, the cost of capital to the firm—the "private" cost—is no longer equal to market cost. For each additional unit of capital input, the firm is permitted to earn a profit (equal to the difference between the market cost of capital and rate of return allowed by the regulatory agency) that it otherwise would have to forego. Therefore, private cost is less than market cost by an amount equal to this difference. The effect of regulation is analogous to that of changing the relative prices of capital x_1 and labor x_2 : isocost curve *B* becomes relevant and the firm moves along expansion path 2—a path along which market cost is not minimized for any given output. The firm finds path 2 advantageous simply because it is along

that path that the firm is able to maximize total profit given the constraint on its rate of return.

Treating the problem mathematically, we now consider a monopoly producing a single homogeneous product using two inputs. Define

$$\begin{aligned} z &= z(x_1, x_2), & x_1 &\geq 0, & x_2 &\geq 0 \\ (1) \quad \frac{\partial z}{\partial x_1} &> 0, & \frac{\partial z}{\partial x_2} &> 0, \\ z(0, x_2) &= z(x_1, 0) = 0 \end{aligned}$$

as the firm's production function. That is, marginal products are positive, and production requires both inputs.

We write the inverse demand function as

$$(2) \quad p = p(z).$$

Profit is defined by

$$(3) \quad \pi = pz - r_1x_1 - r_2x_2$$

where the r_i ($i=1, 2$) are factor costs presumed constant for all levels of factor input.

Let x_1 denote the physical quantity of plant and equipment in the rate base, c_1 the acquisition cost per unit of plant and equipment in the rate base, u_1 the value of depreciation of plant and equipment during a time period in question, and U_1 the cumulative value of depreciation. Let x_2 denote the quantity of labor input and r_2 the labor wage rate. The regulatory constraint is:

$$(4) \quad \frac{pz - r_2x_2 - u_1}{c_1x_1 - U_1} \leq s_1$$

where the profit net of labor cost and capital depreciation constitutes a percentage of the rate base (net of depreciation) no greater than a specified maximum s_1 .

For simplicity, we assume that depreciation (u_1 and U_1) is zero and we define capital so that its acquisition cost or value c_1 is equal to 1, i.e., the value of the rate base is equal to the physical quantity of capital.¹ The "cost of capital" r_1 (to be distinguished from the acquisition cost of plant and equipment measured by c_1) is the interest cost involved in holding plant and equipment. The allowable rate of return s_1 is the rate of return allowed by the regulatory agency on plant and equipment in order to compensate the firm for the cost of capital—the interest

¹ Alternatively, one could construct a dynamic rather than a static model and consider positive values for depreciation; but to do so would complicate the results without contributing much additional insight into the behavior of the firm.

cost—involved in holding plant and equipment. Therefore, the constraint may be rewritten as

$$(5) \quad \frac{pz - r_2x_2}{x_1} \leq s_1$$

or

$$(6) \quad pz - s_1x_1 - r_2x_2 \leq 0.$$

For $s_1 < r_1$, the allowable rate of return is less than the actual cost of capital, and the firm withdraws from the market. For, from (6), if $x_1 > 0$,

$$pz - r_1x_1 - r_2x_2 = pz - s_1x_1 + (s_1 - r_1)x_1 - r_2x_2 \leq (s_1 - r_1)x_1 < 0.$$

If $x_1 = 0$, $\pi = -r_2x_2$ from (3), and the firm can further reduce its loss by setting $x_2 = 0$. Then $\pi = 0$. Therefore, $s_1 \geq r_1$; the allowable rate of return must at least cover the actual cost of capital.

The problem then is to maximize (3) subject to (6).² Define the Lagrangian expression:

$$(7) \quad L(x_1, x_2, \lambda) = pz - r_1x_1 - r_2x_2 - \lambda[pz - s_1x_1 - r_2x_2].$$

The Kuhn-Tucker necessary conditions³ for a maximum at $\bar{x}_1, \bar{x}_2, \bar{\lambda}$ are

$$(8.1) \quad r_1 \geq (1 - \lambda) \left[p + z \frac{dp}{dz} \right] \frac{\partial z}{\partial x_1} + \lambda s_1, \quad x_1 \geq 0$$

$$(8.2) \quad r_1 > (1 - \lambda) \left[p + z \frac{dp}{dz} \right] \frac{\partial z}{\partial x_1} + \lambda s_1 \quad \text{implies} \quad \bar{x}_1 = 0$$

$$(8.3) \quad (1 - \lambda)r_2 \geq (1 - \lambda) \left[p + z \frac{dp}{dz} \right] \frac{\partial z}{\partial x_2}, \quad \bar{x}_2 \geq 0$$

$$(8.4) \quad (1 - \lambda)r_2 > (1 - \lambda) \left[p + z \frac{dp}{dz} \right] \frac{\partial z}{\partial x_2} \quad \text{implies} \quad \bar{x}_2 = 0$$

$$(8.5) \quad pz - s_1x_1 - r_2x_2 \leq 0, \quad \bar{\lambda} \geq 0$$

$$(8.6) \quad pz - r_2x_2 < s_1x_1 \quad \text{implies} \quad \bar{\lambda} = 0.$$

Assuming $\bar{\lambda} > 0$, it is clear from (8.1) that $\lambda = 1$ if and only if $r_1 = s_1$. If $\lambda = 1$, $r_1 = s_1$. This does not involve any variables, and it follows that any x_1, x_2 which satisfies (8.5) is a solution.

² Since (6) is an inequality, we are faced with a nonlinear programming problem. However, the similarity of the results to ordinary marginal conditions is obvious.

³ If the total revenue function, pz , is concave in the relevant range of operation, it is clear that the Kuhn-Tucker conditions in this case are also sufficient. Given a concave pz , it is possible to define the dynamic gradient process corresponding to the static Kuhn-Tucker conditions showing the firm's input variation over time. But we do not do this here since we are primarily interested in equilibrium and the optimal inputs under regulation.

For $s_1 > r_1$, which is the interesting case, it follows that $0 \leq \lambda < 1$: From (8.6), s_1 may be chosen large enough so that $\lambda = 0$ (i.e., at some high level of allowable rate of return s_1 , the value $x_1 (s_1 - r_1)$ exceeds the level of unconditionally maximized profit, and the constraint is ineffective). If we now let $s_1 \rightarrow r_1$, λ varies continuously, and since $\lambda \neq 1$, we have $0 < \lambda < 1$. For the unregulated monopoly, the marginal conditions are:

$$(9) \quad r_i = \left[p + z \frac{dp}{dz} \right] \frac{\partial z}{\partial x_i}, \quad (i = 1, 2).$$

Under conditions of effective regulatory constraint ($\lambda > 0$) equations (8.3) and (9) disclose that, as in the case of unregulated monopoly, the input of x_2 is such that its marginal cost r_2 is equal to its marginal value product. In contrast, equations (8.1) and (9) disclose that the input of x_1 is such that its marginal cost r_1 is greater than its marginal value product,⁴ i.e., its use is expanded beyond the point at which its marginal cost would be equal to its marginal value product.

From equations (8.1) and (8.3) when the equalities hold, the marginal rate of substitution of factor 1 for factor 2 is:

$$(10) \quad \frac{-dx_2}{dx_1} = \frac{r_1}{r_2} - \frac{\lambda}{(1 - \lambda)} \frac{(s_1 - r_1)}{r_2}.$$

Since

$$\frac{\lambda}{(1 - \lambda)} \frac{(s_1 - r_1)}{r_2} > 0, \quad \lambda > 0, \quad s_1 > r_1,$$

then

$$(11) \quad \frac{-dx_2}{dx_1} < \frac{r_1}{r_2}.$$

The firm adjusts to the constraint, then, by substituting capital for the cooperating factor and by expanding total output. Comparative equilibrium outputs are shown in Figure 2. If the regulated firm were constrained to move along the socially efficient expansion path 1 in Figure 1, it would operate at OC in Figure 2. Here price is slightly above

⁴ Clearly

$$\frac{r_1 - \lambda s_1}{1 - \lambda} = r_1 - \frac{\lambda}{1 - \lambda} (s_1 - r_1) \geq \left[p + z \frac{dp}{dz} \right] \frac{\partial z}{\partial x_1}.$$

Since $0 < \lambda < 1$, $s_1 > r_1$, it follows immediately that:

$$r_1 > \left[p + z \frac{dp}{dz} \right] \frac{\partial z}{\partial x_1}.$$

FIGURE 2

average cost AC to reflect the fact that $s_1 > r_1$ (profit is not entirely eliminated). Since the regulated firm moves along path 2, the social cost curve rises from AC to AC' , and the regulatory constraint is satisfied at the lower output OB . The effect of regulation is to force the firm to expand output from the unregulated position OA , but output does not expand to C because a portion of what would otherwise be profit is absorbed by cost. The extent to which regulation affects output depends upon the nature of the production function. If it involves fixed proportions, i.e., $\min\left(\frac{x_1}{a}, \frac{x_2}{b}\right)$, the regulated firm is constrained to the efficient expansion path and it moves all the way to OC . If the production function is linear and if the iso-output curves have a slope equal to $-\frac{r_1}{r_2}$, the firm could substitute x_1 for x_2 and, with no change in marginal rate of substitution, hold output constant. In this case it could remain at OA , the unregulated monopoly output, under the condition that at output OA

$$pz - s_1x_1 - r_2x_2 \leq 0, \quad x_2 = 0.$$

II. The Multimarket Case

Suppose that in addition to operating in a single market, the firm can also enter other regulated markets, and that the regulatory agency

bases its "fair rate of return" criterion on the firm's over-all value of plant and equipment for all markets taken together rather than computing a separate rate of return for each market. In this case the firm may have an incentive (that it would not have in the absence of regulation) to enter these other markets, even if the cost of so doing exceeds the additional revenues. Expanding into other markets may enable the firm to inflate its rate base to satisfy the constraint and permit it to earn a greater total constrained profit than would have been possible in the absence of second markets.

A noteworthy implication is that the firm operating in oligopolistic second markets may have an advantage over competing firms. The regulated firm can "afford" to take (long-run) losses in these second markets while competing firms cannot. Under these circumstances, it is conceivable that the firm could drive out lower-cost producers—the loss it willingly takes in second markets could exceed the difference between its costs and the lower costs of other firms. It may succeed, therefore, in either driving lower cost firms out of these markets or of discouraging their entry into them. This is unlike the textbook case of "predatory price-cutting" where the regulated monopolist may temporarily cut prices in outside competitive markets to drive out rivals and subsequently raise prices to monopoly levels. The monopolist would ordinarily engage in such a practice only if he had the expectation that in the long run he would make a positive profit in these additional markets; but here even in the case of a long-run loss the regulated firm may find operations in such markets to be advantageous as long as the firm is permitted to include its capital input in these markets in its rate base.

Moving to a mathematical treatment, let us consider an extreme example where operating in a second market permits the firm to act as an unconstrained monopoly in the first market, i.e., operating in the second market permits satisfaction of the regulatory constraint such that the firm can operate in the first market at output OA in Figure 2. We shall assume that for any combination of factors along the socially optimal expansion path in market 2 the firm is just able to break even in that market. That is, for any equilibrium x_{12} , x_{22}

$$(12) \quad p_2 z_2 - r_1 x_{12} - r_2 x_{22} = 0.$$

The constraint for n markets is written:

$$(13) \quad \sum_{i=1}^n p_i z_i - s_1 \sum_{i=1}^n x_{1i} - r_2 \sum_{i=1}^n x_{2i} \leq 0.$$

Denoting output and factor inputs in market 1 as \bar{z}_1 and \bar{x}_{11} , \bar{x}_{21} respectively at the output at which profit is unconditionally maximized

in market 1, we have

$$(14) \quad p_1 \bar{x}_1 - s_1 \bar{x}_{11} - r_2 \bar{x}_{21} = m, \quad m > 0$$

where m is the value of "excess" profit in market 1 that would violate the constraint (13) if the firm operated only in market 1. However, by moving along its expansion path in market 2 the firm can choose a level of capital input such that

$$(15) \quad p_2 \bar{x}_2 - s_1 \bar{x}_{12} - r_2 \bar{x}_{22} = -m.$$

Adding (14) and (15) we see that the firm can now satisfy constraint (13) without foregoing any profit in market 1. While the unregulated firm would be indifferent about operating in market 2, the regulated firm in this example finds market 2 attractive because it can add capital to the rate base at "no loss"; i.e., for any capital input in market 2 the output generates revenues just equal to factor cost. Since in market 2 the actual cost of capital is below the allowed rate of return, the firm can apply the difference in satisfying the constraint in market 1 and thereby enjoy additional profit equal to $s_1 - r_1$ for each unit of capital in market 2.

This analysis suggests that even if the firm suffers a loss in market 2 (measured in terms of social costs r_1 and r_2) it may still operate there provided the value of x_{12} ($s_1 - r_1$) exceeds this level of loss. If it suffers a loss it would no longer operate in market 1 at the profit-maximizing output OA in Figure 1; seeking to equate the marginal value product of capital in both markets, it would move toward OB .

In the literature on public utility economics, concern is frequently expressed that the firm will attempt to inflate its rate base to increase its profit. However, the problem is generally viewed as one of proper valuation of rate base, i.e., the firm would always have an incentive to have its property stated at a value higher than its cost. The problem has given rise to a great deal of controversy about proper valuation, especially concerning original versus reproduction cost, and depreciation policy.⁵ In the present study the problem of rate-base inflation is not viewed as one of valuation but rather as one of *acquisition*—quite apart from the problem of placing a valuation upon the rate base, the firm has an incentive to acquire additional capital if the allowable rate of return exceeds the cost of capital.

III. *The Telephone and Telegraph Industry*

Turning to the domestic telephone and telegraph industry, we find that the market structure and the regulatory setting are consistent with

⁵ For examples of the manner in which the problems has previously been treated see [5, Ch. 19, 20] [10, Ch. 12, 17] [14, pp. 515-16].

those described in the model. And the implications drawn from the model, concerning relative factor inputs and incentives to operate in some markets even at a loss, raise issues relevant to assessing market behavior of firms in the industry.

For our purposes, the notable feature of the industry's market structure is that the degree of competition does vary from one subsector to another. Common carriers have monopoly positions with regard to public message telephone and telegraph services, while they compete with each other in supplying private line services to customers who, in addition, are free to construct private wire facilities for their own use as an alternative to purchasing from the common carriers.

The principal supplier of public message telephone service is the Bell Telephone System. Besides the parent corporation, American Telephone and Telegraph Company, the Bell system includes 22 subsidiary "associated" companies of which 20 are primarily or wholly owned by AT&T. Each of the associated carriers provides local exchange and toll service within the state or group of (contiguous) states that comprises its "operating territory."⁶ The Bell system holds about 98 per cent of all facilities employed in long-distance message toll telephone service in the United States, and about 85 per cent of all facilities employed in local telephone service. The remaining 15 per cent of local exchange facilities are in the hands of about 3,200 "independent" telephone firms, most of which are very small. These carriers connect with the Bell system, under service- and revenue-sharing agreements, and provide an integrated nationwide network. Competition does not exist among firms in the public message telephone business. Although many firms are in the industry, each has its own exclusive local marketing area.⁷

In the telegraph field, in contrast to telephone, public message telegraph service is offered only by the Western Union Telegraph Company. This is a much smaller subsector in terms of revenues than public message telephone service. In 1959 Western Union revenues for the former were about \$170 million, while Bell and independent connecting carrier revenues for the latter were \$7 billion.

Bell and Western Union compete in common markets in providing other services. Until recently Bell (together with independent connecting carriers) was sole supplier of private-line telephone service. How-

⁶ AT&T, through its Long Lines Department, provides interstate line and radio facilities to connect the separate operating territories of the associated companies; in addition, in some cases Long Lines participates in providing interstate service internally within the territories of the multistate associated companies.

⁷ A good description of the industry and its present-day market structure is contained in [8, pp. 4-34].

ever, in 1961 Bell and Western Union negotiated facilities contracts⁸ that enable Western Union to offer private-line telephone service in competition with Bell. Western Union and Bell both provide telegraph exchange service and private-line telegraph service—Bell's teletypewriter or TWX service is similar to Western Union's Telex, and Bell's teletype private-wire service is similar to Western Union's leased circuit teleprinter offering. In addition, a new competitive element has recently been introduced: as an alternative to purchasing private-line telephone and telegraph services from the common carriers, firms outside the communications industry may now operate their own microwave facilities to provide communication among their geographically separated plants.⁹

Intrastate services of the common carriers are regulated by individual state regulatory commissions; interstate operations are regulated by the Federal Communications Commission. These agencies use a "fair rate of return" criterion in regulating prices within their respective jurisdictions. The services of each common carrier are generally lumped together in computing the rate of return to be regulated. For example, in regulating Bell's service the FCC routinely considers together all revenues, plant investment, and operating costs of Bell's interstate services in computing a rate of return to serve as the basis for decisions about price adjustments.¹⁰ Likewise, most state agencies compute an over-all rate of return for each carrier for all of its intrastate operations within the state in question.

Since the interesting implications of the model rest on the assumption that the allowable rate of return exceeds the actual cost of capital, the question arises as to whether revenues of the industry do exceed factor costs. While it is impossible to treat this question exhaustively here, there is some reason to believe that revenues are generally in excess of costs. We have been told by representatives in both the industry and in regulatory agencies that justification exists for allowing a return in excess of cost to give firms an incentive to develop and adopt cost-saving techniques. If the firm is left only indifferent as among a wide range of activities it has no positive incentive to mini-

⁸ These contracts permit Western Union to lease Bell communications facilities in order to enter markets that it could not feasibly serve if confined to its own facilities.

⁹ While railroads and public utilities, the so called "right-of-way" companies, have historically been permitted by law to employ privately owned radio communications facilities for their internal needs, it was not until 1960 that the way was cleared (by a final decision of the Federal Communications Commission in Docket 11866) for other firms to provide their own communications facilities.

¹⁰ It is true that special studies of the separate services are occasionally made by the FCC in order to determine individual rates of return. Evidence from one such study will be presented below.

mize costs for any given activity. Consequently, regulatory agencies do not typically view with disfavor rates of return which are (within broad limits) somewhat in excess of rates they would judge to reflect cost. Positive profit is sometimes generated by the "regulatory lag" phenomenon: As the firm adopts new cost-saving technology or as its business volume rises for output subject to decreasing costs, its rate of return rises. However, the regulatory agency does not react immediately to force prices down. Rather, a lag of years may be involved. An example of this can be drawn from the interstate telephone operations of the Bell System. In its over-all interstate operations Bell experienced a decline in its rate of return from 7.5 per cent to 5.2 per cent from 1950 to 1953. Reasoning that a rate in the neighborhood of 5 per cent was too low, it filed revised tariff schedules increasing interstate message toll rates by about 8 per cent—an increase expected to bring the rate of return up to about 6.5 per cent. The FCC, agreeing that earnings under the old tariff were inadequate, allowed the new tariff to go into effect. There is a strong implication in the FCC staff memoranda written at the time that a fair rate of return was considered to be in the neighborhood of 6 per cent.¹¹ After the increase went into effect in 1953, the rate of return rose to 6.6 per cent in 1954, 7.7 per cent in 1955, reached a peak of 8.5 per cent in early 1956, and continued in excess of 7 per cent during 1957 and 1958. Despite an interstate toll rate reduction in 1959, the rate of return amounted to almost 8 per cent in 1959 and 1960. The fact that the rate of return remained above a 6 per cent level during most of the decade meant that for a number of years revenues in interstate operations exceeded the FCC Staff estimate of cost.¹²

One implication drawn from the model is that the firm increases its ratio of capital input to cooperating factor input in a manner that increases social costs at the equilibrium output. Do the common carriers in this industry overinvest in this fashion? Unfortunately, empirical evidence is not available to us on the issue of bias in favor of investment

¹¹ A clear, concise account of the manner in which the FCC regulates interstate telephone and telegraph services is contained in [12, pp. 3427-45].

¹² The rise in Bell's rate of return is partly attributable to Bell's striking success in developing and adopting new cost-saving technology. The average book cost per circuit mile of Long Lines plant declined from roughly \$230 in 1925 to \$30 in 1960. The strong long-run incentives apparent in Bell's activities to cut costs may be construed as *prima-facie* evidence that it enjoys positive profits. Of course, one could argue that another factor is present—entrepreneurship—whose cost would more or less offset the positive profit; i.e., in the economic sense (in contrast to the accounting sense) revenue may just cover cost and the firm still has incentive to minimize cost. But here we are concerned with the *marginal* cost of capital to the firm compared to the *marginal* return to capital allowed by the regulatory agency. If the latter exceeds the former, the "regulatory bias" emerges regardless of whether total cost includes a fixed charge attributable to an additional factor.

in plant and equipment. However, one point should be made: the regulatory agencies exert little direct control over investment decisions that would force the firm to follow the socially optimal expansion path. The FCC, for example, follows a "used and useful" criterion in judging whether a given item is to be included in the rate base of plant and equipment. If the item is being employed in operations, and if it is useful (judged partially on subjective grounds), it is included. While common carriers are required routinely to provide a formidable list of reports concerning current operations, the relatively small staffs of the regulatory agencies available for research and investigative tasks, the lack of satisfactory criteria upon which to make judgments, and the heterogeneity of both factor inputs and service outputs would make extremely difficult if not impossible the task of detecting such bias.

The second implication drawn from the model is that due to the nature of regulation the firm has an incentive to operate in some markets even at a loss. Again, there is no clear-cut evidence which shows whether common carriers in this industry do, in fact, operate at a loss in some markets. However, evidence is available disclosing that (1) fears of "unfair" competition based on operations at "noncompensating" prices play a prominent role as a source of conflict between the carriers themselves and between the carriers and the FCC; and (2) in attempting to establish a commercial communications satellite system, the federal government has enacted a law containing provisions that (to serve "public ends") appear to exploit the willingness of common carriers to operate in markets at a loss. We shall now discuss some of this evidence.

The FCC undertook a study in 1956 of interstate private-line services offered by the common carriers in order to determine the relationship between price and cost for these services on a more precise basis than is possible by considering only the over-all rate of return for each carrier on all its interstate services. In the course of the study Bell submitted data (based on 1955 operations) showing that its telephone grade services were earning at a rate of 11.7 per cent, and its teletypewriter (telegraph) grade services at 2.6 per cent.¹³ On the basis of this evidence, the FCC ordered interim price reductions in telephone grade services (in which Bell at the time was sole supplier) and permitted an increase for both Bell and Western Union for telegraph services (in which the two carriers do compete). The FCC expected the price adjustments to reduce substantially the spread between Bell's rates of return on telephone and telegraph grade services and to increase Western Union's rate of return on telegraph services.

¹³ The initial decision of the FCC staff in this study (not adopted by the Commission at this writing) is contained in [6].

During the study Western Union criticized Bell's behavior that allegedly resulted in Bell's relatively low rate of return on the telegraph services competitive with Western Union's own offerings. In the words of the FCC staff [6, p. 54]:

Western Union refers to evidence of record indicating that during the twenty-year period preceding this investigation, all principal private line telegraph rate adjustments were initiated by AT&T and, with one exception, all were rate reductions. Western Union alleges that AT&T has received a noncompensatory return on its private line telegraph service while enjoying a substantial return from services not competitive with Western Union. . . . According to Western Union, it follows that AT&T has engaged in unfair competition by maintaining unreasonably low rates for a competitive service and shifting the resulting financial burden to other services.¹⁴

Western Union's allegations, if true, would indicate that in conformity with the model, Bell is operating in private-line telegraph at a loss. However, it is impossible, for two reasons, to determine from the evidence in the FCC study whether this is in fact the case. First, the evidence in the record is simply not sufficient to determine what earnings level is "proper", i.e., what earnings level would just cover the cost of capital.¹⁵ Second, the rates of return quoted above are based on "fully allocated cost" as opposed to marginal cost. In our model, the firm operates at a loss in a market only if the additional revenues it receives by operating in that market are below the additional costs it incurs. And whether operations in that market impose a "financial burden" (to use Western Union's words) on the other services depends on whether additional revenues do cover the additional costs.¹⁶ But fully allocated costs are something else again. These include the costs of facilities used solely for the service in question and, in addition, they include an allocation of the "common" costs incurred by the carrier. For example, the telephone instrument itself is necessary in providing both intrastate and interstate message toll service as well as local exchange service; a transcontinental microwave system carries both public message toll and private-line traffic. In computing a rate of return for each of these services, it is necessary to allocate the costs of facilities having multiple uses. In general, the FCC allocates these costs in accordance with relative time of use. If a given facility is employed by service A 50 per

¹⁴ For AT&T's reply see [4, pp. 14-18].

¹⁵ The FCC staff concluded that AT&T's proper earnings levels is $7\frac{1}{4}$ per cent and for Western Union 9 per cent. This conclusion was contested by Bell in its reply brief: "These [FCC staff] findings are made despite the fact that there is not a word of testimony in the record concerning the over-all costs of capital to either carrier, much less the costs of capital for their private line services" [4, p. 3]. See also [2, p. 27].

¹⁶ A good statement of this point is contained in [1, pp. 7-10].

cent of the time and by service B 50 per cent of the time, the cost of the facility is split equally between A and B. For our purposes, however, the crucial question is whether the cost of the facility could have been cut in half if either service A or service B had not been offered.¹⁷ Is allocation on the basis of relative time in use an accurate reflection of marginal costs generated by each service? We may presume an affirmative answer only if the industry is subject to constant costs. However, the available evidence is not sufficient to determine whether the industry is, in general, subject to constant costs in the relevant range of output. If, on the contrary, it is subject either to decreasing or to increasing costs, use of the conventional cost allocation procedures would tend either to overstate or to understate marginal costs for particular services. Because of these possibilities, the rates of return commonly quoted for a particular communications service cannot be used as a reliable guide in determining whether a loss, in the relevant sense, is being incurred in providing that service and whether a financial burden is thereby being imposed upon the other services.

Competition between Bell and Western Union will probably continue to be a lively issue in future FCC investigations. In February 1962, the FCC was reported to have had "under consideration for some time an over-all study of telephone vs. telegraph competition"; in the same month the American Communications Association (a union representing Western Union employees) "formally petitioned for an investigation into the extent and effect of participation by the American Telephone and Telegraph Co. in domestic and international telegraph communications."¹⁸

Our model suggests that apprehension about the nature of competition in the industry is justified since a common carrier, regulated as described above, would (under certain conditions) have an incentive to operate at a loss in competitive markets and to shift the financial burden to its other services. In this sense, it would have an "unfair" advantage over other firms which do not have other markets sufficiently profitable to bear the loss of competing with it.¹⁹ Unfortunately, however, the FCC and other regulatory bodies are so wedded to the fully allocated cost criteria rather than to marginal cost criteria in judging the "fairness" of competition, that evidence drawn from future hearings and investigations will probably not throw much light on the question

¹⁷ For purposes of this simple illustration, we are assuming a zero elasticity of demand substitution between A and B.

¹⁸ [9, February 26, 1962, p. 1].

¹⁹ That is, the unconditionally maximized profits of the other regulated firms may be sufficiently low so that imposition of the regulatory constraint does not induce them to operate at a loss in competitive markets.

whether common carriers in some markets do, in fact, operate at a loss measured in the relevant economic sense.

Finally, the model appears useful in treating economic implications of the Communications Satellite Act passed by Congress in August 1962, after long and bitter debate [13]. The Act specifies establishment of a new, private corporation regulated as a separate entity by the FCC to develop and operate the satellite system. The corporation is to be financed in two ways: (1) It may issue capital stock, carrying voting rights and eligible for dividends, to be sold "in a manner to encourage the widest distribution to the American public [13, Sec. 304 (a)]. Purchase of this stock is also permitted by "authorized" communications common carriers²⁰ subject to the constraint that the aggregate of shares held by these carriers together not exceed 50 per cent of the total shares issued and outstanding. This stock is *not* eligible for inclusion in the carrier's rate base. For convenience in subsequent analysis we shall refer to these securities as "type I securities." (2) The Corporation may issue "nonvoting securities, bonds, debentures and other certificates of indebtedness as it may determine." Communications common carriers are permitted to hold these securities without specified limit, and these securities *are* eligible for inclusion in the rate base of the carrier "to the extent allowed by the Commission [FCC]" [13, Sec. 304 (b)]. For convenience we shall refer to these as "type II securities."

The model suggests that, given the provisions of the Act, communications common carriers would have a special incentive to invest in type II securities, and that their financial support might constitute a partial subsidy for the satellite corporation. By holding type II securities the common carrier incurs an interest cost (r_1) and collects whatever interest or dividends are forthcoming on type II securities (r_1'). Were the carrier unregulated or were the securities not eligible for inclusion in its rate base it would purchase securities only under the condition that $r_1' \geq r_1$. Since, however, the investment in type II securities can be included in the over-all rate base of the carrier, the carrier has an incentive (again under certain conditions) to invest more than would otherwise be the case.

Consider the example where the carrier receives a zero return on its investment in type II securities, i.e., $r_1' = 0$ at all levels of investment; therefore, the carrier suffers a loss of r_1 for each dollar of investment. If, however, the allowable rate of return (s_1) is greater than the interest cost (r_1) the regulatory constraint on the carrier's other services is relaxed, permitting prices and profits to be raised in the other

²⁰ Authorized common carriers presumably would include AT&T, Western Union and eight U.S. overseas radio and cable telegraph companies.

sectors. For each dollar in type II securities, the carrier's over-all profit would *rise* by the value $(s_1 - r_1)$: The loss involved in the investment in type II securities would be more than offset by the increased profits elsewhere resulting from inflation of the rate base and relaxation of the regulatory constraint. The carrier, then, may have an incentive to hold type II securities even if a direct loss is involved.

Two closely related implications arise from this analysis: First, the costs to the satellite corporation of obtaining money capital will fall if it can sell type II securities to common carriers at a return that is below their own interest cost (and if their own rate of interest is no higher than that which the satellite corporation would otherwise have to pay). To the extent that these funds provided at reduced cost to the satellite corporation permit a shift downward in its cost curves, the communications toll rates it charges to users of satellite services would also fall below the level that would have been established had the satellite corporation been forced to resort to conventional financing.²¹

Interestingly, a reduction in satellite communications toll rates by reducing financing costs to the satellite corporation, shifting the burden to other services, was intended by the sponsors of the bill that led to the Satellite Act. Senator Kerr, when introducing the bill to the Senate in February 1962, stated [11, p. 1670]:

[This bill strives for] . . . a privately owned corporation in which the existing American companies engaged in the international communications business would be able to invest, with their investments treated the same as the acquisition of new equipment and thus includable in their rate bases. This important feature permitting the rate of return for all communication services to be spread over a broad base would insure lower charges for communication satellite services.

Second, inclusion of type II securities in the carrier's rate base may permit the satellite corporation to operate even if its total revenues do not cover total market costs. In this case type I securities issues may be small, since little if any dividends would be earned, and the bulk of financial support might come from common carriers holding type II securities at a return below the market rate of interest.²² Again, the losses in satellite operations would be covered by revenues from telephone and telegraph services provided by the carriers.

²¹ These users include both U.S. and foreign international common carriers who would employ the satellite relays primarily for transoceanic communications links in combination with or as a substitute for submarine cable and radio. To the extent that users of the satellite system are the same carriers which invest in type II securities, their subsidy to the satellite corporation would be more or less offset by the reduction in toll rates they pay to the satellite corporation. However the Act specifies no particular relationship between the amount of type II securities they respectively hold and their relative use of the satellite system.

²² In this case type I securities would be attractive primarily because of the voting rights they confer.

IV. *Conclusions*

The preceding analysis discloses that a misallocation of economic resources may result from the use by regulatory agencies of the rate-of-return constraint for price control. The firm has an incentive to substitute between factors in an uneconomic fashion that is difficult for the regulatory agency to detect. Moreover, if a large element of common costs exists for the firm's outputs in the various markets, the widely used "fully allocated" cost basis for rate-of-return computation is likely to prove unsatisfactory in determining whether the firm is operating at a loss in any given market, or whether its activities in some markets tend to restrict competition in an undesirable manner. At the same time, regulatory practices that provide an incentive for the firm to operate in some markets even at a loss may constitute a convenient mechanism through which certain activities of the firm judged to be in the "public interest" can be subsidized.

Our analysis suggests lines of further inquiry: We have considered only the telephone and telegraph industry, but the issues raised by the model may be relevant to evaluating market behavior in other industries as well. It is notable that Gardner Means in a recent study [7] has advocated that certain large nonregulated firms judged to be "collective enterprises" be encouraged, by tax incentive, to engage in "target pricing" where they aim for a profit equal to a fair rate of return on investment. By following this approach to pricing, which is similar to that employed in public utilities, the danger exists (which he does not recognize) that these firms would be exposed to the same pressures discussed above of inflating their rate bases by substituting capital for labor and by expanding into unprofitable new lines in order to satisfy the authorities that they were using "proper" target pricing. It might prove worthwhile to examine the effect of target pricing in steel and other industries discussed by Means in the light of the preceding analysis. Furthermore, it might be interesting to explore alternative forms of government control that, by avoiding the return-on-investment criterion for price regulation, do not generate the bias disclosed here.

COMPETITION AS A DYNAMIC PROCESS

A Review Article

By MYRON W. WATKINS*

Professor Clark's new study¹ confirms his reputation for keen observation, subtle analysis and rare detachment. Nevertheless it is a disappointing book. For measured against the author's bold aims, the results are minuscule. The stated objectives of the inquiry are: (1) to synthesize neoclassical economic theory and the Chamberlin-Robinson monopoloidal doctrines derived mainly from the fewness of sellers in specific markets and the practice of product differentiation; and (2) to provide, or at least to point the direction in which the outlook is favorable for developing, some new "dynamic tools of economic analysis" (preface, pp. ix, x).

In pursuit of the first objective, the inquiry is analogous to the age-old dialogue between Platonists and Aristotelians. As usual, the attempted reconciliation of opposites goes forward here through exploration of the feasibility of a "middle way" involving accommodation from both extremes. In effect, for Clark this process consists mainly of underlining the monopolistic tendencies that neoclassical theorists often ignored and of heavily discounting the monopolistic tendencies inherent in a situation where sellers are few and products are differentiated. The upshot is a persistent emphasis on the beneficent role of big business as it has developed willy-nilly and as it currently operates. Of course, a "synthesis" of opposites (in this case, of competition and monopoly) thus effected is illusory. It represents no solution of the problem, but simply a denial of its existence.²

* The author has recently retired from professional practice as business consultant. He wishes to acknowledge helpful criticism of an earlier draft from F. H. Knight and A. E. Kahn.

¹ J. M. Clark, *Competition As a Dynamic Process*. Washington: Brookings Institution, 1961. Pp. xvii, 501. \$7.50.

² For this reason the quest of syntheses to resolve fundamental antitheses is perennial. The method may succeed in "dissipating," or at least in rendering *hors de combat*, one or both of the opposite theses but it leaves a gap, still, between them. In philosophy, as in all the sciences, this issue will not down. Some men are convinced that "truth" lies only in generalizations, principles, laws, ideas or "ideals"; others are no less firmly, one might say congenitally, committed to the view that truth can be found only in particulars, data, specifics. The recurrent controversy on this issue among historians has recently been probed and brilliantly illuminated by a signally erudite scholar in the George Macauley Trevelyan Lectures at Cambridge University, winter 1961. See Edward Hallett Carr, *What is History?* (New York 1962). His perspicacious analysis in Chapters 5 and 6 should be particularly meaningful for economists in their present theoretical dilemma.

On the second objective, the failure to reach any clearly defined results may be traceable in part to the author's nebulous method of exposition. Presumably he was looking for supplements to various conceptions of demand functions and cost behavior that would lead to formal rules, perhaps even measuring devices, for computing the "allowances and adjustments" that should be made in taking account, mainly, of "changes over time" in conditions (on both sides of the market).

The reviewer is not aware how the frequently repeated charge can be substantiated that neoclassicists, for all their "static" premises, ignored changes in "conditions" either environmental or internal. They did premise competition; and is not the essence of competition uninhibited initiative in introducing and meeting technological changes, style changes, *et cetera*, in short, experimentation? Did any reputable neoclassicist assume absolutely unchanging technological or market "conditions"? Did they not all believe in and advocate "progress," at least, all of them after, say, the 19th century, when events had rolled back iron laws and Malthusian clouds into limbo?

The reviewer ventures the view that the author's difficulty in identifying and specifying new "dynamic tools of economic analysis" stemmed partly from the *ad hoc* nature of his own ventures into making "allowances and adjustments" for "changes over time." These excursions generally turn out to represent alibis, excuses, or extenuations of what would otherwise pass as predatory arrangements; or, less frequently, vice versa as explanations of the bad effects of maneuvers that, on their face, appear innocent, if not indeed beneficent. The situations or practices conceived to merit *special* treatment in the interests of the common welfare are distinctive features or structural patterns of particular firms, industries, or groups. For all practical purposes they are unique. The "adjustments" indicated are correspondingly special. They are hardly amenable to being subsumed under logical categories or types. (See Ch. 17.)

Another point to be stressed is that in all of these "special" cases the ultimate criterion of whether a practice or a situation warrants some "adjustment," whether positive or negative, in market regulation is departure from what "would be" the outcome of competition, not a *lutte à l'outrance*, but competition in some ideal sense. It is competition "vigorous enough to result in prices no higher than a *normal* competitive level for the industry" (p. 53; and see Ch. 6, 7; emphasis supplied). Such "vigorous enough" competition is repeatedly referred to as "a healthy kind and degree of competition," or some such equivalent as "yielding normal profits." Of course, the former phrase, which appears to be one of the author's favorite expressions, is egregiously ambiguous. Yet he can hardly be criticized for the use of such a nebulous concept. To have been more precise would have been to expose himself, we feel certain, to far more biting criticism. Nevertheless, if this concept is to be taken as a "dynamic tool of economic analysis," does it not need sharpening?

Quite broadly, the system of the "maverick" John Maurice Clark as set forth in the present volume corresponds closely to that of the "orthodox"

John Bates Clark.³ In both cases, the distinctive characteristic is the combination of a strong bias in favor of the fundamental postulate of free competition, a beneficent "principle," the continuing efficacy of which, "in the large," is in neither case subjected to critical examination, with a resolute determination to leave no stone unturned in attempting to reconcile with it the "stubborn facts." Compared with the elder Clark's exposition of the essentials of economic theory, the younger Clark's "system" as here propounded is predicated on a more relativistic awareness of the contemporary importance in market-adjustment processes of the factor of time, and of the incessant variation in environmental circumstances. The son's theory is plainly less rigid and mechanistic than the father's. But though more elastic, and in most respects more equivocal too, it would be a fair judgment, we believe, to say that its basic premises and major outline bear a close resemblance to that of John Bates Clark. This assessment is by no means derogatory.

In this connection it may be observed that the practical consequences of how the "competitive" order actually works in a "dynamic" world are in the *Essentials* all reserved for discussion in the last third of the book. Perhaps this accounts, in part, for the fact that the "dynamic" features of this neo-classicist's theory have been largely overlooked. John Bates Clark did not "worship a graven idol." He drew much of his theory, taking his work as a whole, from searching scrutiny of contemporary conditions. If he dwelt at times in an ivory tower, he used it as an observation post and his vision was not obscured by colored glasses. He had clear eyes. Significantly, he plainly anticipated (*Essentials*, p. 201) the major finding of a school of theory which became popular a quarter century later. "There is a question," he said, "whether, after competition has reduced the establishments in one sub-group [of industry] to a half dozen or less, they would not, even without forming a trust, act as a quasi-monopoly." From the context it is clear that the term competition is used here in its generic sense, embracing not only the emulative rivalry, which alone Clark approved, but also the predatory type aiming at liquidation of rivalry or extermination of rivals.

Granting that John Maurice Clark is a more vigorous, trenchant, and resourceful analyst of "competition in practice" than were most members of the neoclassical school, including his father, it can hardly be said that, in the present volume, he justifies his aspersions on the "equilibrium theorists," or his pretension of being a "trail blazer." For decades it has been customary among economists of all schools to make "allowances" for "conditioning factors" affecting market behavior, including alike sluggish response to competitive opportunities and overaggressive response to challenging "moves" by others. These "realistic" qualifications on the adequacy or even propriety of "competition in action" were intensified and highlighted, of course, by the

³ As expounded in *The Essentials of Economic Theory* (New York 1907). J. M. Clark is also careful to avoid trenchant criticism of Alfred Marshall's work. See e.g., Ch. 19, esp. pp. 475-76. Of the basic elements of "orthodoxy," as interpreted by Thorstein Veblen, only the hedonistic calculus is absent, at least outwardly, in the present study. See Veblen's analysis of "Professor Clark's Economics" in Thorstein Veblen, *The Place of Science in Modern Civilization and Other Essays*, New York 1919, pp. 180-230.

work of the so-called institutional school. That institutionalists did not call such attempts to reconcile theory and facts efforts to evolve "dynamic tools of economic analysis" does not make their so-called "descriptive analysis" any less significant. But it may help to explain the reader's inability to discover signal contributions to theory in Clark's enterprise in this direction. At any rate, the reviewer, with full awareness of the continuity of developments in economic theory, has the feeling that in this undertaking the author has added little to the profession's work-a-day equipment.

It is difficult to understand the organization of this study of how competition (or should one say pseudo-competition?) could be "saved"—saved alike from suicide and from socialism. The book is divided into 19 chapters. In the best textbook tradition, each chapter has a paragraph or two of prologue and of recapitulation at its terminal points. In addition, subdivisions averaging about seven per chapter identify by topic headings the major subjects discussed in each chapter. Nevertheless the reviewer found it hard to hold firmly in mind the main thread of the discourse. The study seemed to him, consequently, to lack cohesiveness.

Lest other readers experience a similar bafflement, he proposes a tentative alternative arrangement of the major divisions of the work. Conscious of the fact that the author's inquiry was avowedly exploratory, a probing venture, and that the suggested rearrangement of the textual outline may do an injustice to the author's intentions, the reviewer hopes that in any case his suggested alternative outline may assist prospective readers to proceed with a clear understanding of what to look for.

Chapters 1 through 7 comprise a useful introduction and reconnaissance. They survey the development of theories of how competition works, or should work, to adjust supply and demand, of the influence exerted on this adjustment process by costs of varying kinds and magnitudes, as well as of the sources of pressures and pulls exerted on demand. These chapters emphasize the significance of the emergence in this century of a radical but uneven change in the pace of technological advance and the accompanying alteration in the methods of production and distribution (marketing). All this is introductory to the formulation (in Chapter 8) of the problem with which the author's inquiry is mainly concerned: how to smooth the way to, and the way from, innovations.

The ensuing ten chapters (Chapters 9 through part of Chapter 18) comprise the main body of the study and might well be denominated Part II. Chapters 9 and 10 in this section might appropriately be entitled "The Relation of Product Differentiation to Market Structure and Pricing." Chapter 11 could be fairly described as "Market Structure and Pricing Under Product Homogeneity." Chapters 12, 13 and 14 are devoted to what the author calls "Competition at a Distance," which will be recognized as the root of the situation that gave rise to basing-point systems. Chapters 15-18 might usefully be combined, and for such a chapter one might borrow the title actually employed for Chapter 15, "Related Problems and Practices." This group includes a discussion of target pricing, of the influence on market structure and pricing of (a) big buyers, (b) special situations—integration, diversification, patents—,

and (c) unionism. Of course, the foregoing suggested revision of chapter headings and the arrangement of the study does not provide an exhaustive index of the full range of analysis in this section. For that matter neither does the author's table of contents. However, such a revision may serve to indicate more clearly the scope of discussion and help the reader to comprehend its bearing on what the author conceives as the most pressing contemporary economic problem: how to foster "economic progress," or more specifically, how to encourage innovations without diminishing over-all efficiency.

The third and final section (Part III here, consisting much of Chapter 18 and all of Chapter 19) might be designated "Conclusions." It does not consist of a summary of the argument and findings in the preceding ten chapters. Rather, the author's procedure in these pages is to inquire (in the light of the analysis in suggested Part II) into ways of attaining dynamic, healthy competition (a) by forestalling inflation, (b) by providing appropriate and dependable information, (c) by encouraging mobility, and (d) by coordinating the diversely rising rates of productivity in and among the several major branches of the economy, thereby smoothing its development.

From the title as well as from the author's prefatory announcement of the objective of his study, one might expect a clear definition of "effective competition." While Chapters 2 and 3 represent an endeavor to distinguish this concept from the sort of marketing process it was the object of the antitrust laws to foster and which the courts have consistently sought to preserve or restore, the discussion makes it clear that Clark's main preoccupation is to differentiate his concept from the theories of "imperfect" competition with their "monopoloidal" implications (pp. 50-52).⁴ Regarding the essentially semantic squabbling over the right term for designating a pattern of business organization intermediate between the conceptual extremes of perfect competition and monopoly, both of which concepts have been recognized all along as solely analytical devices without reality, there is no occasion here to challenge Clark's terminological choice.

But it is in devising a practicable alternative to these models that Clark lets the reader down. Certainly his shift of terminological allegiance from "workable" to "effective" competition in no way contributes to clarification of the central problem: how to distinguish from ineffective competition the real competition that theorists (including Clark, pp. 365-66, 486, *et passim*) invoke as a norm and that, in effect, the law enjoins.

The nearest approach to a definition of "effective competition" that the re-

⁴ Clark's animus to deflate the "monopolistic competition" theorists and thereby introduce some measure of support, excuse, or respectability for the "limited competition" he defends is indicated by the following passage (p. 51), among many others (e.g., Chapter 9, especially pp. 212-40): "On the normative side, the prevalent types of theorizing have one outstanding common characteristic. They tend to a finding that any feasible form of competition in industry and trade is defective in the same direction which monopoly is defective and to an extent that may be equivalent to the defects of monopoly, or less, or in some cases even more. . . . This is true . . . especially of the theories of E. H. Chamberlin. In relation to his theories, the present study could be regarded as an attempt to build a positive treatment on assumptions, many or most of which Chamberlin admits or leaves room for as exceptions or departures, but the significance of which he does not develop."

viewer encountered reads: "For . . . competition to be effective, the crucial thing seems to be that prices be independently made under conditions that give some competitors an incentive to aggressive action that others will have to meet whenever prices are materially above the minimum necessary supply prices at which the industry would supply the amounts demanded of the various grades and types of products it produces" (p. 18).⁵ This definition illustrates the author's tendency to shy away from an unequivocal statement. Nevertheless, for professional economists it is clear enough, though some might question whether the long qualifying clause beginning "under conditions" adds much besides verbiage. Do not the qualifications make for fuzziness of the conception of what is "crucial"? At least they leave unresolved the question of what objective tests can be applied to a pattern of market organization or of business behavior to determine its compatibility with the public interest or, more specifically, with "progress."

The feature of the current situation that sets the stage for a "reformulation of competitive theory" (p. 418) such as the author essays is that "competition tends to be overly strong in some sectors of the economy and insufficiently effective in others. . . ." (p. 486). *Inter alia* these differences in the strength of competitive forces often arise from, but more commonly and significantly lead to, disparities in the rate of technological advance, thereby impeding progress. Progress seems to be defined mainly in the form of increasing rates of "labor productivity" as the term is customarily employed (output per employee per time period). But it is reflected most clearly, it seems, in the rise of per capita real income in the community at large or perhaps even among wage-earners alone.

Disparities among firms and industries in the rate of progress give rise to the more insistent economic problems. In this category fall the socio-economic problems which Clark identifies by such catch-words as "inflation" (pp. 175, 272-80, 449-50, *et passim*), "sticky prices" (pp. 432-38), and perhaps also, in this category, "agriculture" (pp. 277-80, 302-4, *et passim*). Specific business practices also come in for analysis which is often, but not invariably, sketchy, though seldom superficial. However, the analysis of basing-point systems is neither sketchy nor superficial. It occupies no less than three chapters (pp. 299-362). In view of Clark's well-known preoccupation—and defiant lone wolf position—with respect to basing-point systems, no surprise need greet this concentration of all his resources and skill in the attempt to prove the economic defensibility, at least in such circumstances as those in the cement industry, of what he here calls "competition at a distance." The present writer will not review the controversy (ably and objectively summarized by the author). He would affirm only that this section is the clearest and most persuasive segment of the study, though he doubts whether it will change the views on this controversial subject of many members of the American Economic Association.

The discussion of sticky prices, spiraling wages, and inflation (pp. 432-59) is competent and incisive, judged by current standards in the analysis of fac-

⁵ See, also, p. 288 for a similar definition with comparable qualifications.

tor-sharing of the joint product, but hardly throws new light on price-level determinants. The analysis of advertising or sales promotion (pp. 84-85; 217-43) the reviewer found the least acute of any part of the study. It reflects the author's catholicity of outlook. It also illustrates well his bent toward taking account at least nominally of all factors conceivably involved in the adoption of a given practice, as well as of those in some degree or in some circumstances conditioning its results. This bent is in no sense to be denigrated per se. But unless it is kept in check with an extremely cautious regard for the relative importance of the several factors and contingencies it tends to lead, as here, to prolix exposition. It may account for the characteristic ambivalence and ambiguity in the author's comment on this burgeoning business practice. Speaking of the costs of selling efforts "necessary to familiarize the buyers with the new products and popularize them," Clark declares (pp. 84-85) that "if any considerable fraction of the effort so spent yields cumulative improvements in our level of living, this cumulative improvement outweighs *whatever fraction* of our resources we devote each year to bringing it about. We should like to reduce the waste and increase the serviceability. But most economic students would prefer an economy actively energizing its productive resources and progressing annually, with an amount of waste motion, to one with less waste motion and less employment of resources or slower economic progress. The former represents the direction in which institutions of market research and sales promotion are energetically steering the American economy."⁶ Manifestly, the stated trend has Clark's approval. But the reviewer wonders how the author discovered that "most economic students" agree with him.

Consider, also, the over-all vagueness of the following judgment (p. 53) on product differentiation ". . . it seems clear that product differentiation brings in an added dimension of competition, and . . . on balance . . . in the light of available remedies for accompanying defects, this outweighs any contrary effects it may have, especially in the light of progressive effects over time. In that light it appears that the kind of demand that goes with product differentiation is favorable rather than unfavorable to a healthy kind and degree of competition, unless the slope of the demand function is unduly steep . . . , or unless it brings advantages of size that unduly reduce numbers and restrict free entry. In these cases, product differentiation would afford a substantial shelter from competitive pressure. But in the more usual kinds of cases, it is quite consistent with competition vigorous enough to result in prices no higher than a normal competitive level for the industry. . . ." So? If we bear in mind the widespread adoption of this marketing device, a paraphrase of Jurgen's favorite response in argument may not be inappropriate here: "You may be right. Certainly I would not go so far as to say you are entirely wrong. Still, at the same time. . . ."

The general impression that a careful reading of this book gives is that Clark has scrutinized a broad area of the contemporary economic landscape and with his usual penetration uncovered significant new aspects of several

⁶ Emphasis added. Note the number of questions begged in this brief passage.

baffling problems. His discursive method enables him to offer solvents that under ideal conditions might well ameliorate the acute discord and distressing disarray that plague an economy experiencing a technological *bouleversement*. Nevertheless it appears to the reviewer that the study makes little advance toward its professed objectives. As indicated, the methodological synthesis proposed turns out to be only a deflation of a straw man, perfect competition, on one extremity and the erection of a dubious angel, enlightened competition, on the other. However, the reviewer salutes the survival in this generation of an eminent economist who is prepared to eschew, even to deride, the fashionable resort to rigid mathematical models.

COMMUNICATIONS

On the Theory of Expansion of the Firm¹

Economists who have spent time observing the operations of business enterprises come away impressed with the extent of management's occupation with growth. Expansion is a theme which (with some variations) is dinned into the ears of stockholders, is constantly reported in the financial pages and in the journals devoted to business affairs. Indeed, in talking to business executives one may easily come to believe that growth of the firm is the main preoccupation of top management. A stationary optimum would doubtless be abhorrent to the captains of industry, whose main concern is surely not at what size their enterprises should finally settle down (except where sheer size endangers their standing with the administrators of the antitrust laws) but rather, how rapidly to grow.²

Although the static theory of the firm is a helpful snapshot description of a system in motion,³ it is useful also to have an alternative construction of the kind which is described in this paper—another equilibrium analysis in which the *rate of growth* of output, rather than its *level*, is the variable whose value is determined by optimality considerations.

I. A Simple Growth Equilibrium Model

For simplicity the first model is confined to a case in which input and output prices are fixed (pure competition), and where the production function is linear and homogeneous. Thus I am either dealing only with the period of time before the firm grows so large that the prices become variables which are

¹ This paper owes much to the growing literature of the dynamics of the firm. Particularly, I am indebted to Robin Marris for permitting me to read his unpublished manuscript [5] and to Herbert Frazer who wrote his doctoral dissertation on the subject. Highly relevant and stimulating is Edith Penrose [7]. In addition I owe much to the work of Richard E. Quandt [8, esp. pp. 156-66]. I am also very grateful for their comments to A. Heertje, Fritz Machlup, Burton Malkiel, Richard Quandt, Harold Shapiro, and John Williamson. Finally, I must express my great appreciation to the National Science Foundation whose grant helped materially in the completion of this manuscript.

² This view is not unrelated to one of Kaldor's well-known arguments. See N. Kaldor [3]. Here the author reminded us that equilibrium of the competitive firm requires some sort of increasing costs to make it unprofitable for the company to expand indefinitely. But under pure competition there seems to be no obvious source of diminishing returns, and hence little reason for *any* scale of operations of the competitive firm to constitute a long-run stationary equilibrium situation.

³ Thus I am emphatically *not* proposing that the conventional theory of the firm be relegated to the garbage heap or the museum of curious antiquities. Static analysis of a nonstationary phenomenon can be immensely illuminating, and the received theory of the firm contains many very helpful results, both from the point of view of the understanding of the workings of the economy and the applied work of the operations researcher. It would be folly to deny ourselves the use of this body of analysis just because its domain of applicability is somewhat limited.

subject to the influence of the firm, or we must assume that all firms grow together and that in this process no one of them outgrows the others sufficiently to constitute it a significant force in the market. This premise permits me to evade the problem of demand for the expanding outputs of the firm. So long as it operates under conditions of pure competition its demand curves will be perfectly elastic and no marketing problems will affect its plans.⁴

It is assumed that management considers only a very simple growth pattern—a fixed percentage rate of growth, to be continued into the indefinite future. This heroic assumption is adopted to permit a simple characterization of the optimal growth path by means of a single variable, the permanent percentage rate of growth, g .⁵

Finally, it is assumed, at least for the moment, that the company's objective (which determines the optimal rate of growth of its output) is conventional profit maximization.

It is posited that costs can be divided into two categories: ordinary production and operating costs, and costs which arise only as a result of the expansion process. That is, any costs which would be associated with a given level of output if the output rate were not changing may be classed under output costs; any additional outlays above and beyond the output costs are called expansion costs. Output costs will only be taken into account implicitly, in the net revenue figures. That is, in discussing revenues, net revenue figures, from which output costs have already been deducted, will be employed.

Let R represent the initial net revenue of our firm, g be the rate of growth (which is to be determined), and i be the rate of interest relevant in discounting future revenues. Then, because of the constancy of the prices of all of the firm's inputs and outputs and the linear homogeneity of the production function, net revenues will grow precisely in the same proportion as inputs. Thus, in t periods, the firm's net revenue will be $R(1 + g)^t$, and the discounted present value of that net revenue will be $R[(1 + g)/(1 + i)]^t$. The present value of the expected stream of revenues will therefore be:

$$(1) \quad P = \sum_{t=0}^{\infty} R \left(\frac{1 + g}{1 + i} \right)^t = R \frac{1}{1 - \frac{1 + g}{1 + i}} = R \frac{1 + i}{i - g},$$

⁴ However, if all firms expand simultaneously in this way they may encounter secularly declining prices and problems of Keynesian excess supply. This macroeconomic problem is not discussed here since it merits being considered by itself in some considerable detail. I have elsewhere taken the optimistic position that if all firms expand rapidly enough they will usually create sufficient purchasing power to constitute a market for their products. No doubt many readers will question this hypothesis which appears to be a distant relative of the Say's Law family.

⁵ If this premise is not employed and the optimal rate of growth at every future moment of time is left to be determined, we are forced in to the morass of the theory of functionals and we cannot escape without at least some recourse to the calculus of variations.

provided only⁶ that $g < i$ so that $(1 + g)/(1 + i) < 1$ as is required for convergence of the geometric series (1).

It is perfectly obvious in this situation that we have

$$(2) \quad \frac{\partial P}{\partial g} > 0,$$

that is, the present value of the net revenue stream will grow indefinitely with the rate of expansion g . In fact, P will grow at an increasing rate with g , and its value will exceed any preassigned number as g approaches i , as shown in the net revenue curve, RR' in Figure 1. There is clearly nothing here to place a limit on the rate of expansion of the firm.

The firm will only be constrained from accelerating its activities without limit by its expansion costs, the present value of which we designate as $C(g)$. The literature is replete with discussions of the administrative costs of growth and there is no point in recapitulating these materials here. It is enough to point out that growth is what strains the firm's entrepreneurial resources and adds to the company's risks, and it may be expected that after some point the resulting increases in costs will catch up with the marginal revenues derived from more rapid expansion.⁷ That is, it may be assumed that the slope of the cost curve CC' , which is the graph of the function $C(g)$, will normally be less than that of RR' near the horizontal axis, but that eventually the slope of the former will catch up with and finally exceed that of the latter. (It may be, however, that in some cases the slope of the cost curve will ex-

⁶ The problems caused for such a model if the rate of growth exceeds the rate of interest are well known. Specifically, the geometric series (1) will then not converge and the present value of the firm's profit stream will no longer be finite. See, e.g., David Durand [2]. However, as Miller and Modigliani have shown, the case $g > i$ is not a serious possibility. They write [6, fn. 14]: "Although the case of (perpetual) growth rates greater than the discount factor is the much-discussed 'growth stock paradox' . . . it has no real economic significance. . . . This will be apparent when one recalls that the discount rate, . . . though treated as a constant in partial equilibrium (relative price) analysis of the kind presented here, is actually a variable from the standpoint of the system as a whole. That is, if the assumption of finite value for all shares did not hold, because for some shares g was (perpetually) greater than i , then i would necessarily rise until an over-all equilibrium in the capital markets had been restored." (The notation has been changed from the original to that employed in this paper.)

An alternative way of avoiding this problem is to drop the (unrealistic) premise that the horizon is infinite. However, a finite horizon (say one involving 5 periods) will yield an expression for total revenue which is somewhat more messy than (1). Though it will be a fifth-degree polynomial, it will have only positive coefficients and so any equilibrium will still be unique. Indeed, the results of the infinite horizon model all seem to continue to hold in the finite horizon case.

⁷ This view of the shape of the cost function can also be defended with the aid of the usual (somewhat shaky) appeal to the second-order maximum conditions. For, given the shape of our revenue function, the cost curve must behave in the manner shown in Figure 1 or there would be no profit-maximizing growth rate.

Note also that C is likely to be a function of other variables in addition to g , i.e., it is apt to depend on the initial absolute level of output—a small firm is likely to find it less costly to expand 10 per cent than does a large company. However, since $C(g)$ is the present value of all expected future costs taken together, initial cost differences may not play a very important role.

FIGURE 1

ceed that of the revenue curve throughout the positive quadrant so that the optimal growth rate will be zero negative.)

Specifically, we obtain the growth-profit function:

$$(3) \quad \Pi = P - C(g) = R \frac{1+i}{i-g} - C(g).$$

The profit-maximizing conditions are then (using the notation Π_g for $\partial\Pi/\partial g$, etc.),

$$(4) \quad \Pi_g = P_g - C'(g) = R \frac{1+i}{(i-g)^2} - C'(g) = 0,$$

(the first-order marginal revenue equals marginal cost condition), and

$$(5) \quad \Pi_{gg} = 2R \frac{1+i}{(i-g)^3} - C''(g) < 0,$$

the second-order condition.

Graphically, the equilibrium rate of growth is given by Og_e in Figure 1, the value of g at which the slope of the expansion cost curve CC' and that of RR' are equal.⁸

⁸We might even envision a long-run zero-profit competitive growth equilibrium in which entry has caused shifting of the curves and produced a zero-profit tangency position at which growth level has settled. There is some question in my mind whether, in a growth model such as this, much relevance can be ascribed to that type of long-run adjustment.

II. Comparative Statics in the Analysis of the Model

This simple growth model can easily be made to yield some results in terms of comparative statics. While some of these are not particularly surprising, they may offer some reassurance that the model does not possess particularly perverse properties, and that it can serve as an instrument of analysis much like the standard stationary equilibrium model.

First, a rise in the interest rate will reduce the present value of the stream of expected revenues, for we have⁹ by (1)

$$(6) \quad P_i = R \frac{(i - g) - (1 + i)}{(i - g)^2} = -R \frac{1 + g}{(i - g)^2} < 0.$$

Moreover, a rise in the interest rate will reduce the *marginal* revenue yield of increased economic growth, P_g , for we have, differentiating (6) partially with respect to g ,

$$(7) \quad P_{ig} = P_{gi} = -R \frac{(i - g)^2 + 2(i - g)(1 + g)}{(i - g)^4} < 0$$

by our basic assumption $g < i$.

It is now rather simple to prove that (at least in a perfect capital market where some market rate of interest determines the relevant discount factor) a rise in the interest rate will reduce the equilibrium rate of growth of the firm. For differentiating the first-order maximum condition (4) totally and setting $d\Pi_g = 0$ (so that the equilibrium condition continues to hold) we obtain:

$$d\Pi_g = P_{gi}di + \Pi_{gg}dg = 0$$

or

$$(8) \quad \frac{dg}{di} = -\frac{P_{gi}}{\Pi_{gg}} < 0$$

by (5) and (7).

Geometrically, this obvious result is a consequence of the fact that a rise in i reduces the slope of the RR' curve in Figure 1 throughout its length, as indicated by (7), so that the equilibrium growth level, Og_e , must move to the left.

A somewhat more interesting application arises out of the recent proposals

⁹A complication is introduced by the fact that interest payments are among the output costs which have been subtracted from our net revenue figure, R , so that R should no longer be treated as a constant when differentiating with respect to i . This can be taken care of by noting that our assumptions of linear homogeneity and constant price imply that the quantity of money capital employed by the firm should be strictly proportionate with $R(1 + g)^t$. Say it will equal $ikR(1 + g)^t$ and therefore incur an annual interest payment, $ikR(1 + g)^t$. In that case we need merely write $R = R^*(1 - ik)$ and make this substitution in our revenue function (1). It may then easily be verified by direct differentiation that the resulting expression for P_i will be slightly more complicated than (6) but that it will still be negative. A similar remark holds for (7) and (8).

to stimulate business growth by means of appropriate government subsidies.¹⁰ Suppose one is considering two alternative subsidy plans for this purpose. The first plan involves payments (S_{1t}) proportionate with the percentage rate of increase of the firm's output growth,

$$S_{1t} = s_1 g_t = s_1 g.$$

The present value of all such expected future subsidy payments is

$$(9) \quad S_1 = s_1 g \sum_{t=0}^{\infty} \left(\frac{1}{1+i} \right)^t = s_1 g \left(1 + \frac{1}{i} \right).$$

The alternative plan proposes to offer a stream of subsidies (S_{2t}) proportionate to the absolute rate of increase of output:

$$S_{2t} = s_2 [R(1+g)^t - R(1+g)^{t-1}] = s_2 g R(1+g)^{t-1}$$

whose capitalized present value is:

$$\begin{aligned} S_2 &= \frac{s_2 g R}{1+g} \sum_{t=1}^{\infty} \left(\frac{1+g}{1+i} \right)^t = \frac{s_2 g R}{1+g} \left[\left\{ \sum_{t=0}^{\infty} \left(\frac{1+g}{1+i} \right)^t \right\} - 1 \right] \\ &= \frac{s_2 g R}{1+g} \left[\frac{1+i}{i-g} - 1 \right] = \frac{s_2 g R}{1+g} \cdot \frac{1+g}{i-g} \end{aligned}$$

or

$$(10) \quad S_2 = \frac{s_2 g R}{i-g}.$$

Adding, in turn, the subsidy expressions (9) and (10) to our basic profit function (3) we obtain the two new profit expressions:

$$(11) \quad \Pi^* = R \frac{1+i}{i-g} - C(g) + s_1 g \left(1 + \frac{1}{i} \right)$$

and

$$(12) \quad \Pi^{**} = R \frac{1+i}{i-g} - C(g) + \frac{s_2 g R}{i-g}.$$

By the same procedure as was employed when the effect of an interest rate change was examined, we arrive at the respective comparative statics results:

$$(13) \quad \frac{dg}{ds_1} = - \frac{1 + 1/i}{\Pi_{gg}^*} > 0$$

and

$$(14) \quad \frac{dg}{ds_2} = - \frac{iR}{\Pi_{gg}^{**}(i-g)^2} > 0$$

¹⁰ For example, in the Kennedy administration 1961 investment credit proposals. See also Klaus Knorr and W. J. Baumol [4], whose suggestion seems, in substance, to have been adopted by the Canadian Government (House of Commons, *Proceedings*, Apr. 10, 1962, pp. 2706-7).

if the second-order conditions $\Pi_{gg}^* < 0$ and $\Pi_{gg}^{**} < 0$ both hold. Thus both types of subsidy would, indeed, stimulate the growth of the profit-maximizing firm.

We can go beyond this somewhat uninteresting conclusion by asking which of these two types of subsidy will yield more growth per dollar of government outlay. For this purpose we must deal not with s_1 and s_2 , the subsidy rates, but with the total subsidy outlays, S_1 and S_2 , as given by (9) and (10). From these we obtain:

$$(15) \quad \frac{ds_1}{dS_1} = \frac{1}{g(1 + 1/i)}$$

and

$$(16) \quad \frac{ds_2}{dS_2} = \frac{i - g}{Rg}.$$

Multiplying (13) by (15) and (14) by (16) and writing out the expressions for Π_{gg}^* and Π_{gg}^{**} we obtain:

$$(17) \quad \frac{dg}{dS_1} = - \frac{1}{g\Pi_{gg}^*} = - \frac{1}{g \left[2R \frac{1+i}{(i-g)^3} - C''(g) \right]}$$

and

$$(18) \quad \begin{aligned} \frac{dg}{dS_2} &= - \frac{i}{g(i-g)\Pi_{gg}^{**}} \\ &= - \frac{i}{g \left[2R \frac{1+i}{(i-g)^3} - C''(g) + \frac{2is_2R}{(i-g)^3} \right] (i-g)}. \end{aligned}$$

Hence subsidy S_2 will yield higher marginal returns than subsidy S_1 if and only if expression (18) exceeds expression (17), i.e., if and only if

$$- \frac{1}{g\Pi_{gg}^*} < - \frac{i}{g(i-g) \left[\Pi_{gg}^* + \frac{2is_2R}{(i-g)^3} \right]}.$$

This requires

$$(i-g) \left[\Pi_{gg}^* + \frac{2is_2R}{(i-g)^3} \right] > i\Pi_{gg}^*$$

or

$$-g\Pi_{gg}^* + (i-g) \frac{2is_2R}{(i-g)^3} > 0$$

and since (because $\Pi_{gg}^* < 0$ by the second-order condition) both terms in this last expression are positive, this requirement will always be satisfied. We conclude that in our model a subsidy of the second type will then always yield higher marginal growth returns than does a subsidy of the first type.

It is also noteworthy that a net investment tax credit of the sort originally proposed is essentially equivalent in our model to a growth subsidy proposal of type two. For the investment credit is a subsidy proportionate to the level of net investment. With our linear homogeneous production function, and with constant input prices, the capital-output ratio will be constant so that a subsidy proportionate to investment will automatically be proportionate to the absolute rate of increase in output.

Since so many other considerations must enter any decision among alternative growth stimulation methods there is no point in laboring this discussion further. The case serves, however, to illustrate how meaningful theorems can be derived from the growth equilibrium model of the firm.

III. *Profit versus Growth Maximization*

The discussion so far has been confined to the case of pure competition and has assumed that the firm's objective is to maximize profit. But larger *oligopolistic* firms may well have a different set of objectives.¹¹ Specifically, I have suggested that management's goal may well be to maximize "sales" (total revenue) subject to a profit constraint. Though I remain firmly convinced of the merit of the hypothesis as a static characterization of the current facts of oligopolistic business operation, in the present context—a growth equilibrium analysis—it is desirable to modify the hypothesis in two respects.

First, maximization of *rate of growth* of sales revenue seems a somewhat better approximation to the goals of many management groups in large firms than is maximization of the current *level* of sales. For example, most company publicity materials seem to emphasize the extent to which the firm has "progressed" rather than the sheer magnitude of its current operations. In my earlier static model I was forced to employ a sales-revenue-level objective as an approximation to a measure of the rate of growth of the firm's scale of operations. A growth equilibrium model now frees me from this necessity.

The second modification deals with the nature of the profit constraint, which in a static model may have seemed to be arbitrarily imposed from the outside—perhaps even a device to avoid explaining what had to be explained, very much like the fixed mark-up of doubtful origin which lies at the heart of the full-cost pricing discussions. A growth analysis enables me to give an explanation of the profit constraint which, I hope, is somewhat less superficial and rather more convincing.

From the point of view of a long-run growth (or sales) maximizer, profit no longer acts as a constraint. Rather, it is an instrumental variable—a means whereby management works towards its goals. Specifically, profits are a means for obtaining capital needed to finance expansion plans. Capital is raised both by direct retention of profits and by the payment of dividends

¹¹ See [1], esp. Ch. 6-8.

to induce outside investors to provide funds to the company. But, beyond some point, profits compete with sales. For the lower prices and higher marketing outlays which are necessary to promote sales also cut into net earnings. Hence, too high a level of profits will reduce the magnitude of the firm's current operations, while too low a profit level will prevent future growth. The optimal profit stream will be that intermediate stream which is consistent with the largest flow of output (or rate of growth of output) over the firm's lifetime.

Specifically, this optimal profit rate can be described with the aid of a simple model such as the following:¹²

Let

g represent our firm's growth rate,

I be its level of investment as a per cent of the value of current capital assets (the percentage rate of growth of the firm's money capital),

Π be the profit rate as a per cent of present equity¹³

D be the dividend as a per cent of present equity, and

E be the retained earnings as a per cent of present equity per unit of time.

The objective then is to maximize:

$$g = f(I, \Pi)$$

subject to¹⁴

$$I = \phi(\Pi, D) + E$$

$$\Pi \equiv D + E.$$

The first of these equations, the objective function, expresses the competitive relationship between growth and profit rates, and states that the rate of growth of the firm's operations varies (directly) with investment, and (after a point) inversely with the profit rate (as indicated in Figure 1). The next equation, however, shows that the profit rate indirectly assists growth by providing capital through retained earnings, and by attracting funds from outside sources at a rate, $\phi(\Pi, D)$, which depends both on the dividend rate and the company's profit rate. From this system we can then determine the optimal profit rate, Π , which from our long-run point of view enters into the

¹² For present purposes there is no need to take explicit account of such decision variables as prices, advertising outlay, etc.; but the model can easily be expanded to do so.

¹³ In practice, of course, different profit rates may be optimal at different points in the company's history. But in the fixed-price constant-returns-to-scale model which is employed here there is no reason to depart from a single optimal profit level.

¹⁴ Perhaps, in accord with the Miller-Modigliani view [6] that dividends do not matter, D should be omitted from the ϕ function. Other possible variables that have been suggested for inclusion as elements which significantly affect the willingness of the public to supply funds to the firm are $d\Pi/dt$ —the rate of growth of the firm's profit rate, and g , the rate of growth of its output.

It has been suggested that other, partly conventional, constraints are imposed by the capital market and should be incorporated in a more elaborate version of the model. These include restrictions on the debt-equity ratio, on the ratio between current assets and sales, and on the extent of reliance on noninternal financing.

constraints just as one of the variables in the system. Only in a static sales-maximization model, then, does profit appear as an independent datum arbitrarily given from the outside—a fixed minimal profit requirement which has somehow to be met by the firm.

Substantive theorems for a (sales) growth maximization model may be developed which contrast its consequences with those of profit maximization.¹⁵ However, these propositions are completely analogous with those which I have already developed elsewhere for the case of sales maximization. For example, the growth maximizer's sales, advertising outlay, and (trivially) his growth rate will be larger than those of the profit maximizer and the pricing and output decisions of only the former may be expected to vary in response to changes in fixed costs. Since the logic of these results in our present analysis is exactly the same as it was in the sales maximization model there is no point in repeating the argument here.

I will only suggest what appears to be the most important point, that our discussion has shown the standard apparatus of marginal analysis and mathematical programming to be fully applicable to decision problems even when management's objective is not the venerable profit maximization of economic theory.

¹⁵ It is sometimes stated or implied that long-run growth and profit maximization must necessarily lead to identical decisions and results (see e.g., Penrose [7, p. 29]). But if, as in our model, it is sales rather than assets whose growth is being maximized, or if, even in the long run, investment in the firm can fall short of or exceed profit earnings, it is extremely easy to find counterexamples. In fact, only in the most unusual circumstances would sales (revenue) growth maximization be achieved by the maximization of profits.

The End of the Golden Age in Solovia: A Further Fable for Growthmen Hoping to Be "One Up" on Oiko

Few accidents of timing could be more unfortunate than that which led to the publication of the first definitive account [2] of the discovery and attainment of the "golden age" in Solovia on the very eve of the outbreak of the savage and destructive civil war now being waged in that country. Nor could any course of events be more calculated to add to the bewilderment of those who had been tempted to hope that, at last, here was a piece of economic analysis which could be put into practice. Readers may be interested therefore in this first report of the causes of the revolt put together by the writer on information supplied by academic friends from the (now destroyed) National University of Solovia.

Great things have small beginnings and it appears in this case that all would have been well but for the intelligent curiosity of Alice, the nineteen-year-old granddaughter of Oiko, who, since her historic adventures into Wonderland, was well aware that things are often not quite what they seem. Alice's thinking developed along the following lines.

At first she accepted, like every properly indoctrinated Solovian of the post-Oiko era, that capital must be accumulated at the constant growth rate (g). This was at this time an article of faith not to be questioned. "But," she reasoned, "I do not really want to do my share of saving quite in this way. I am young. I should like to save hard now, to dissave heavily in middle life when the expenses of raising and educating a family are greatest, and perhaps to dissave slightly less heavily in retirement. Provided that *on the*

FIGURE 1

average over my life I have accumulated capital at the rate g , will this properly discharge my debt to society?"

As, by her plan, future generations of Solovian youth would inherit precisely the same amount of capital as if Oiko's rule had been strictly followed and since at no point of time would there be less capital in existence than under Oiko's rule, it seemed to Alice that no one could object. But she had become very cautious since her disconcerting encounter with Humpty Dumpty, so she drew a diagram (Figure 1) to confirm her impressions.

Along one axis she measured time (t) and along the other capital per head (K/N). Any point t_0 , $(K/N)_0$ is evidently associated with a certain level of output per head (Y/N) which would be produced at a time t_0 if at that time $(K/N)_0$ units of capital per head had been accumulated.

Alice quickly found that equiproduct contours, defining all points with the same output per head, take the general shape shown, given the Cobb-Douglas production function:

$$(Y/N) = (K/N)^{\alpha} e^{\rho t}$$

known to be appropriate to the Solovian economy. The value of (Y/N) evidently increases as the point t , (K/N) moves north-east.

The problem now is to discover the arc defining the optimal growth of K/N over time. Alice began by marking in the golden rule (Oiko's) path; that is, where K/N grows at the rate of $(g-\gamma)$, where γ is the population growth rate, and where the position of the path is such that at every moment of time, t_0 , the marginal product of capital remains constant and equal to g . To identify this she constructed a $t = t_0$ sectional map of her diagram (see Figure 2),

FIGURE 2

noting that consumption per head is maximized when the marginal product of capital (equals the interest rate?) equals the rate of growth g , and that in these circumstances saving per head $= gK/N =$ share of capital in the product per head according to Oiko's law.

Alice next estimated the number of people in the population of her own age whom she thought might share her views about personal saving and calculated the approximate path of accumulation if the government could be persuaded to let them have their way.¹ This was now marked on the diagram (Figure 1) and labeled Alice's path, $t = 0$ being taken to be the present and $t = t_1$ the date when the generation concerned could reasonably be expected to have ceased to take any active interest in Solovian affairs. The reader should note that this does not by any means imply that Alice's time horizon is any more finite than Oiko's. On the contrary her acceptance of the obligation to accumulate capital at the rate g on the average means that she recognized society's wish to accumulate at that rate forever.

Alice was now thoroughly puzzled. How could Oiko's path be optimal when it was evident (1) that at *every* point of time between 0 and t , her own path yielded greater total output per head; (2) that the total cost (in terms of consumption foregone) of following her own path would be precisely the same as the total cost of following Oiko's whilst in terms of utility her own path would cost less than Oiko's since she began by defining it as preferred; and (3) that generations living beyond time t_1 would clearly be unaffected by either choice.

Friends were consulted but, unfortunately, it proved difficult to persuade anyone to look at the diagram or listen to the reasoning. All this, it was said, has been solved by Oiko. How could Oiko possibly be wrong when here, in the market place, anyone could see the great statue erected in his honor?

Argument from authority is always impressive but Alice recalled how her grandfather, in his later years, would tell, with no more than a properly controlled trace of pride, how he had reached his "solution" long before the mathematicians despite their understanding of "extremals, functionals and Hamiltonians." Could it be that mathematicians did know something which Oiko did not? Alice took her puzzle to the university.

The professors were very kind. They looked at her diagram and congratulated her upon discovering so much. The younger members of the staff talked learnedly of "end points" and "singular arcs with corner points," and of Euler, Legendre, and Weierstrass necessary conditions. But an older professor explained more simply why Alice was partly right and partly wrong.

He readily agreed that the argument as set out by Alice was formally correct provided that her generation alone followed any path to the right of

¹ Alice was, of course, very well aware of the possibility that if *everyone* in every age group adopted her savings pattern, or something like it, a remote chance existed that the net effect of the changes would be zero and that accumulation might continue as under the Rule. This point is taken up later. The assumption that her generation alone were to follow her savings path, whilst everyone else followed the Rule, was introduced simply to demonstrate that the Rule does not after all maximize total consumption per head between times t_0 and t_1 .

AB. More would be produced at no extra cost so that everyone could be better off. But the implications of the discovery needed to be carefully stated.

Suppose that to exploit the possibilities now revealed the government sought to make the community as a whole follow some path like Alice's between *A* and *B* with the intention of maximizing total consumption of the representative consumer who is assumed to exist at every moment of time between 0 and t_1 . Suppose again that, to escape the accusation of shortsightedness in their policy (i.e., possession of a finite time horizon), the government further decreed that capital at time t_1 must be the same as it would have been under the Rule, can such a policy succeed? The answer, the professor explained, is yes up to a point. Certainly Oiko's path is *not* optimal in this sense although it purports to be.

Alice's argument seems to suggest that a path should be chosen between *A* and *B* as far to the right of Oiko's as possible, but this does not allow for the effect of the continuous growth of population at the rate γ . Increased production due to extra saving in the first few years might not be enough to compensate the representative man for his early effort when account is taken of the increased population in computing his share. On the other hand there does exist an optimal path which is not Oiko's and which can easily be found as follows.

We have to choose some arc between *A* and *B* (Figure 1) which maximizes the expression

$$\int_{t=0}^{t=t_1} \left[\left(\frac{K}{N} \right)^\alpha e^{\rho t} - \gamma \frac{K}{N} - \frac{d(K/N)}{dt} \right] dt,$$

that is, we have to maximize the sum, over the period, of output per head less the saving needed to maintain K/N at the existing level in the face of population growth, less the cost of accumulation per head, the net figure being total consumption of the representative individual. This looks like a problem in the calculus of variations but is in fact a rather special case.

Euler's necessary condition for a maximum [1, p. 529] if applied, requires

$$(1) \quad \alpha(K/N)^{\alpha-1} e^{\rho t} = \gamma$$

which gives K/N as a function of time t and is itself a unique path on Figure 1. In point of fact the path (1) does not pass through *A* and *B*. On the contrary it defines a constant-rate-of-growth path (of K/N) through *C* and *D*, which must lie to the right of Oiko's path as long as ρ is not zero. The application of Euler's condition tells us nothing in the first instance about an optimal path between *A* and *B*. What it does tell us however, is that if we chose end points *C* and *D* then any deviation from the path *CD* would *reduce* consumption. In particular the path *CABD* is a deviation from *CD* and would give less consumption per head than *CD*. That is, the path *CA + AB + BD* gives less consumption than *CD*;

$$\text{or } CA + AB + BD < CD$$

$$\text{and } AB < CD - CA - BD = AC + CD + DB.$$

Hence the path $ACDB$ from A to B gives greater consumption per head than Oiko's direct path AB . Indeed this argument holds for any arbitrary path from A to B as well as Oiko's path so that $ACDB$ is optimal.

Clearly the path CD marks a rightward limit to Alice's path beyond which consumption of the representative man would begin to diminish if the community as a whole were induced to follow it. That CD lies to the right of Oiko's path, AB , is clear from Figure 2, since AB is the path where the marginal product of capital is equal to g and CD is the path where the marginal product of capital is equal to γ . And Oiko's law itself shows g to be greater than γ provided ρ is not zero.

The professor now pointed out that if the rate of population growth were zero then Alice's argument would hold without modification; for with the Cobb-Douglas production function the marginal product of capital never reaches zero however much capital is accumulated. Any path from A to B lying to the right of Oiko's path would yield a greater consumption per head on the average. If population growth is not zero however Alice's path will certainly yield greater consumption per head only if it lies to the right of Oiko's path and does not cut CD . If it should cut CD it may or may not yield higher consumption per head on the average than Oiko's path. This simply reflects the fact that it is never profitable to accumulate capital per head beyond the point where its marginal product is less than the marginal cost, γ , of keeping it at that level.

In other words, if the intention is to maximize consumption per head on the average, without qualification, the path $ACDB$ should be followed. Capital should be accumulated at an infinite rate in the first unit of time until C is reached. It should then grow at the rate g to D . To reach B capital should then be decumulated at an infinite rate in the last moment of time before t_1 . This is, of course, no more than a modification of Alice's "common sense." If we are indifferent to changes in the timing of our consumption between the "end" points $t = 0$ and $t = t_1$, and if consumption can be increased by decumulation of capital, clearly it is better to hold as much capital as possible, provided it earns more than it costs, for as long as possible; for we thereby enjoy the fruits of its productive power.

Alice was about to ask why, if a "crash" program is appropriate to attain Oiko's path without any thought of its cost, do we not introduce a crash program to attain the path CD ? And above all, what is the meaning of Oiko's maximizing condition if his path between A and B is not optimal. But the professor went on to explain that Oiko's law was based upon the implied assumption that it is *impossible* to move from A to B *except* along the golden age path. The golden age path is optimal only in the sense that, beginning from any point on the K/N axis which might be attained by a crash program, we can define a possible path to a corresponding (unique) point on the line $t = t_1$ reached by growth at the constant rate $(g - \gamma)$;² and, of this infinity

² In the special case of the Cobb-Douglas production function it is possible to identify each of these paths by its unique (forever) savings ratio. The Rule then becomes a rule for determining the optimum savings ratio. In countries other than Solovia however, Cobb-

of paths, AB maximizes consumption per head on the average. Alice's path, and every other variable growth rate path, is excluded from consideration by the assumption of constant growth. Alice noted at once the answer to her unspoken question. Clearly by Oiko's law more consumption per head is enjoyed whilst moving from A to B than would be enjoyed whilst moving from C to D , but more still might be enjoyed by moving along her own path from A to B .

The professor continued, "If ρ were zero evidently (from Edmund Phelps' account of Oiko's law) the paths AB and CD would be coincident; for in this case g would be the same as γ . Technical change is a major villain of the piece. If we could be sure that technical change would cease at some finite time the two curves AB and CD would converge. In this case a *crash* program should be designed to take us to C , Oiko's law notwithstanding. This assumes of course that maximum consumption per head is the objective."

Alice now tried a somewhat different line. "I began," she said "without any thought of discovering how to increase consumption per head. I simply wished to change the timing of my capital accumulation. How does this now fit into the problem?"

The professor replied that in fact Alice had been making explicit the simple truth that what most people would like to do is to maximize, not consumption per head, but *utility* from consumption per head. Alice's statement of her wishes made it clear that, for her, utility depended on time as well as consumption per head. The choice of path between A and B is now quite clearly a problem in the calculus of variations. What Alice wished to do was to maximize:

$$(2) \quad \int_{t=0}^{t=t_1} \psi \left[\left(\left[\frac{K}{N} \right]^{\alpha} e^{\rho t} - \gamma \frac{K}{N} - \frac{d}{dt} \frac{K}{N} \right), t \right] dt$$

between the end points A and B , where ψ is a utility function depending on consumption (C) at time t , and t itself. This problem, he went on, was extensively studied by F. Ramsey many years before Oiko was born, so that much of Alice's problem could be understood at once. Only incidentally did it happen that Alice could choose a path which increased utility, ψ , not only on account of intertemporal changes of consumption, exploiting the variable t in ψ . But also more obviously on account of increased aggregate consumption itself. When the function Ψ is introduced it is often a question of balancing one of these factors against the other. No longer would the path $ACDB$

Douglas production functions might not be appropriate. Only with the very limited class of production functions of the form

$$Y = \Phi(K, [Ne^{\rho t}])$$

is it true that a constant (forever) saving rate leads to a constant capital-growth rate. If there really were powerful reasons why only constant growth rates of capital should be admissible the problem of choosing an optimal initial stock is elementary whatever the production function. To find an optimal constant (forever) savings ratio, however, is much more difficult in general.

be optimal even if it could be attained in practice. It could not even be said that the new compromise path must lie between AB and CD . Conceivably it could lie to the left of AB . Moreover the choice of path is immeasurably complicated by the fact that individual preferences differ. A great deal of Alice's hoped-for intertemporal consumption substitution could be attained by suitable borrowing and lending between individuals within the community. The required "net" accumulation of capital might be provided for by suitable government fiscal policy combined with earmarked loans to industry.

Alice was quick to seize upon this last point. "Let us suppose that this can be done; does the problem then reduce to one of maximizing the total consumption in the period of the 'representative' man? Such a policy would clearly give the greatest aggregate quantity of goods to be shared. How it is to be shared is then a subsidiary problem. Clearly the best *practicable* path from A to B is that which maximizes the rate of capital accumulation until the line CD is reached (i.e., by a crash program), and which then continues accumulation at the rate $(g - \gamma)$ until a point on CD is reached where no further saving at all would just carry the community back to B at time t_1 . People in their middle years experiencing their greater costs and who, accordingly, did not wish to join in the early heavy savings program might borrow from those younger, paying back their debts as their expenses grew less."

Alice concluded this argument rather lamely by conceding that the cost and inconvenience of borrowing and lending between individuals so as to fit individual plans to an arbitrary over-all pattern might well not be compensated for by the increased output attained.

The professor smiled sadly. "Even more important, why choose A and B as end points? What is the virtue of Oiko's crash program leading to A ? And what is the virtue of the point B ? Oiko's celebrated lemma, 'Each generation in a boundless golden age of natural growth will prefer the same investment ratio, which is to say the same natural growth path,' clearly depends again on the assumption that nothing is possible other than a constant rate of growth. For if we were now at C as a result of the activities of our forefathers we could perhaps reach B with no saving at all and hence with much greater consumption. Even if the present generation aimed at some level of capital per head at time t_1 , greater than D , future generations would bless us the more however much they believed in Oiko's rule. For the right to diminish the stock of capital is a right which increases consumption whatever views are held about the virtues of a golden age.

"Why in fact do we ever aim to raise the living standards of future generations at our own expense? Suppose we did not. Suppose that on the contrary we set out to keep consumption per head constant. Such a policy would yield an unambiguous path defined by the condition,

$$(3) \quad \left(\frac{K}{N}\right)^{\alpha} e^{\rho t} - \gamma \frac{K}{N} - \frac{d\left(\frac{K}{N}\right)}{dt} = \frac{C}{N}$$

where C/N is the constant consumption per head. This is a differential equation describing a one-parameter family of curves. The appropriate parameter is determined by the initial stock of capital. Such a time path might well involve a running down of capital stocks."

"Against this," objected Alice, who was beginning to understand, "many people feel they would like to give their children a 'better start in life' than they themselves enjoyed." The professor looked pleased. "Precisely! In the dark ages before Oiko each individual was permitted to choose his own savings path just as you wished to do. Presumably at that time choices were made so as to maximize a utility expression of the type (2). End points would have been chosen according to private feelings about what it is desirable to pass on to children. In some cases, of course, this may have been a secondary consideration, the main factor in the choice of end point being a desire for power or the control of productive assets for their own sakes. Unfortunately the individual could not foresee technical change, nor could he foresee the effect on his own income of his savings plan, but observation of the rate of profit might well have given some indication. Suppose, for example, each individual attempted to maximize the expression:

$$\int_{t=0}^{t=t_1} \psi \left[\left(rk + E - \frac{dk}{dt} \right), t \right] dt$$

where r is the profit rate, E is expected annual average earnings, and k is individual capital accumulation. Provided r and E remain independent of k and provided the rate of profit properly reflects the marginal product of capital we have a solution [1, p. 538] which is formally the same as that for aggregate problem.³

"Does this mean," asked Alice, "that the golden age of Solovia is not a golden age from the point of view of welfare? And if so why do professors at the university not seek to make this known? Ought we to go back to uncontrolled savings plans determined by each individual?"

³At this point the original manuscript included a paragraph suggesting that constant growth rates imply that the marginal utility (to the community) of consumption must grow over time also, despite the growth in consumption per head. I am grateful to Phelps for a comment which led me to discover a sign error in the argument on which this conclusion was based.

In fact negative time discounting, in the sense above, is certainly implied only for constant growth paths to the right of the path CD (Figure 1). To the left of CD negative time discounting may or may not be implied according to the strength of diminishing marginal utility (time constant).

Indeed if utility were measured simply by the logarithm of consumption per head, C , being completely independent of time, the application of the Euler condition for an optimum [1, p. 538] to an expression of type (2) gives:

$$\alpha(K/N)^{\alpha-1} e^{\rho t} - \gamma = \frac{1}{C} \frac{dC}{dt}$$

which is Oiko's path. The rate of growth of capital per head (see Figure 2) equals the rate of growth of consumption per head.

This is not the only possible utility function of course. Evidently others could be found with either negative or positive time discounting of marginal utility according as the partial elasticity, with respect to consumption, of the marginal-utility-of-consumption function is numerically greater or less than unity.

The professor again looked sad. "For reasons already given it is not necessarily true that an individual who chooses a savings plan to maximize his utility *ex ante* will in fact maximize it *ex post*. The profit rate is not independent of every individual savings plan. And even if it were so we cannot assume that it is 'best' for the community that every individual should maximize his utility as he sees it. There are many arguments for growth which the individual cannot consider *in vacuo*. For example, the fastest growing country may attain the greatest political and military power. We might even wish to raise output per head beyond the point where consumption per head is maximized solely to bring into existence an emergency stock of capital.

"Unfortunately there do not always exist answers, even in principle to every question which can be put. This is particularly true of questions which include the words 'optimum' or 'best.' What is best is often a matter of what we can all agree is best. Solovia believes that a constant growth rate is best. Therefore it is best and Oiko's rule defines the best of the best. Moreover, how is it possible to argue that Oiko's path is not optimal if it is impossible to identify some other path which is?"

"But," objected Alice, "this brings me back to where I began. If I accept Oiko's path as best then I can easily show that my path is better. You yourself have justified my end points. I will now argue for my path between them. Such a path must clearly leave everyone better off in any sense of the word."

"Argue for it by all means," said the professor, "but take care you do not thereby loose a jinni from the bottle which it will not be easy to recapture. Remember also that your argument depends upon the assumption that all paths are possible. Distinguished economists from at least one renowned university would almost certainly claim that output cannot be represented by the kind of production function which we believe is appropriate to Solovia, or indeed by any aggregate production function at all. Although we do not believe this to be true of Solovia, it has been suggested that certain factors of production can be used only in fixed proportions in such a way that only constant growth rates are possible without technological unemployment of men or machines."

The professor's final warnings proved to be prophetic. Alice felt a little cross and slightly cheated, her feelings being, she thought, rather like those she had experienced after her encounter in Wonderland with a certain caterpillar.⁴

In a search for spiritual consolation she approached her friend, Thor, a rising young politician whose golden voice was alleged to have caused teenagers to scream with delight. By the use of certain weapons by which the weaker sex have throughout the ages proved themselves to be the stronger sex, Alice contrived to get Thor to listen to her argument and to understand the central point. Indeed so successful was she in this that scarcely two weeks had passed before Thor reached the essential stage of believing that he had first thought of the whole thing himself.

⁴The conversation which took place on this occasion has been reported elsewhere.

Thor did not, of course, fully understand all of the professor's points. He was astute enough to recognize, however, that the simple claim that a new capital accumulation policy, attractive to his own generation, could increase consumption per head above that planned, would provide him with a powerful electoral platform. He quickly convinced a number of associates. A new party was formed which took the title "The Young Ones," adopting as a kind of slogan a popular song of that title.

At first the new party succeeded only in attracting a great deal of publicity without making much progress. They did however claim that they were supported in their arguments by the economists at the university. This claim alarmed the "capitalist" community who, since Oiko, had prevailed upon the government to exempt profits from taxation on the grounds that all profits were in any case invested whereas all wages were spent on consumption. It followed, they had argued, that all government consumption must come out of wages if the community were to save at Oiko's "ideal" rate.

Attacks were made in the press on the interference in public affairs of "intellectuals" out of touch with reality. At this point a group of professors made the mistake of attempting an objective assessment of the truth. This proved to be completely unintelligible to the majority except insofar as it appeared to give authoritative support to the anti-Oiko group. The Young Ones were soon submerged as a political force, their argument being taken up by the official opposition party who, objecting in fact to the exemption of profits from taxation, seized the opportunity to reject Oiko's rule on the ground that it had been "shown" to be wrong.

The situation rapidly deteriorated to the point where the civil war began which has led to so much destruction of the country's capital stock.

The End of the Golden Age in Solovia: Comment

1. The first result in Pearce's paper is that the capital-stock path which maximizes cumulative per capita consumption in any finite interval of time is generally not the Golden Rule (*GR*) path.¹ Even if the economy begins and is constrained to end in *GR* equilibrium (end-points *A* and *B* in his Figure 1),

¹Along the *GR* path, capital and output grow at the same constant rate, while investment equals profits (under pure competition and constant returns to scale). Therefore, in *GR* equilibrium, the profit rate on capital and the growth rate of capital (output) are equal. See my original article (p. 641), or the Symposium on Production Functions and Economic Growth in the *Rev. Econ. Stud.*, June 1962, 29, 155-267, *passim*.

the maximizing path departs from the exponential *GR* path between the end points if (and only if) there is technical progress. Specifically, it is maximizing to accumulate capital faster at first—driving the profit rate down to the population growth rate as quickly as possible—and to decumulate the “excess” capital at the last possible moment—raising the profit rate back to equality with the natural growth rate.

There is clearly no contradiction between this result and the results presented in the Growth Fable. I analyzed exponential paths, Pearce analyzed deviations from them. Moreover, at the substantive level, Pearce’s result contains no implications for the desirability of the *GR* investment policy. Pearce’s *ACDB* path achieves greater consumption in the future (and on the average) only at the cost of less consumption in the present. The *GR* path is still “efficient”: no alternative path can offer more consumption than the *GR* path at any point in time without its offering less consumption at some other point in time. Therefore, Alice is mistaken to say of her path, which is qualitatively similar to Pearce’s path, that “[It] must clearly leave everyone better off in every sense of the word.” Alice’s path does not dominate the *GR* path, and so the choice between them is purely a matter of preference.

2. Pearce writes that Solovia’s *GR* policy required every individual to accumulate capital at the natural rate of growth. Alice preferred to save differently, and this fact appears as a *prima facie* argument against the desirability of the *GR* policy.

But the *GR* policy could be carried out through a government budgetary surplus (deficit), coupled with the purchase (sale) of public or private securities. This would make individuals free to save and bequeath whatever they desired in the fiscal-credit environment created by government.

3. No one who has read the Growth Fable could suspect me of earnest devotion to the Golden Rule. It would be silly to make exponential growth a constraint on policy. Even if we wished to choose only among exponential paths, nothing in my paper proves or suggests that the *GR* path is on some criterion the optimal path—in view of the immediate consumption cost of increasing the capital-output ratio to its *GR* level when the initially given ratio is below that level; or the immediate consumption gain of reducing the capital-output ratio below its *GR* level when the initial ratio is above or equal to the *GR* level.

Let us take for granted that we do not wish necessarily to grow exponentially. Should we forget Oiko, like a bad dream? Is Oikonomics an impractical subject? Does it say nothing about desirable growth, or undesirable growth?

The message of the Growth Fable is that under certain conditions investment policy can be too thrifty, boosting the associated time path of output by less than the associated path of saving—hence lowering the consumption path. One rigorous implication of my analysis is that any constant capital-output (constant profit rate) path which sustains the capital-output ratio at a level in excess of its *GR* value is dominated by a policy which gobbles up the “excess” capital immediately and subsequently maintains the capital-output ratio at its *GR* value. Therefore, any investment policy which at some stage

permanently fixes the capital-output ratio at a level exceeding the *GR* level is inefficient and cannot be optimal (since a policy to be optimal must be optimal at every stage).

An obvious generalization of this result suggests itself, although any proof of it would apparently have to go beyond the analysis in my paper: Any policy which causes the capital-output ratio permanently to exceed—always by some minimum finite amount—its *GR* level is inefficient and hence cannot be optimal. Pearce's *ACDB* path and Alice's path pass this first test for optimality because they are only temporary deviations from the *GR* path; the supra-*GR* capital is consumed in the end.

The Elasticity of the Marginal Efficiency Function: Comment

In his very stimulating treatment of the properties of the marginal efficiency function, Lorie Tarshis examined the effects of riskiness on the elasticity of investment by employing a hyperbolic marginal efficiency function [3, pp. 969-77]. This of course provided him with a curve of constant elasticity and hence supplied a secure basis from which to develop his results. Thus he showed that, if the risk allowance is constant over all projects or if the allowances differ but are random with respect to expected yields, the function adjusted for risk is less elastic than the unadjusted one. Although these results support the usual claims that risk reduces elasticity, Tarshis pointed out that over a wide range of circumstances the introduction of the risk allowance would not necessarily transform an elastic unadjusted function into an inelastic one. He then considered the case where the risk allowance is a fixed proportion of the expected yields. Here the introduction of risk produces no effect on the elasticity—a result which clearly contradicts the effect usually attributed to risk.

Had Tarshis used the linear instead of the hyperbolic function as his special case he could have (1) handled each of the three conditions more simply, (2) reversed the elasticity effects for the first two cases and thus raised even greater scepticism about the effects of risk on elasticity, and (3) obtained a stronger result for his last condition. Whereas the use of the hyperbolic relationship conveniently provides a function with constant elasticity, the linear relationship makes use instead of the property of constant slope. This feature also gives rise to a function which, at successively higher levels of investment, shows decreasing elasticity. Whether either a function with decreasing elasticity or one with constant elasticity is a reasonable one is, of course, an empirical question. This is not an issue which we shall pursue here (other than to note that in at least one recent empirical study of the effect of the interest rate on investment, the authors explicitly express a preference for a linear function over a hyperbolic one [1, p. 85]). Rather,

FIGURE 1

we shall simply provide the linear counterpart for each of the three cases Tarshis considered.

Case 1. The risk allowance is the same over all investments: Representing in Figure 1 the linear unadjusted marginal efficiency function by MM and the risk allowance by b percentage points, M_1M_1 becomes the adjusted function. Now the elasticity is given by:

$$\begin{aligned}
 e &= - \frac{dI}{dr} \cdot \frac{r}{I} \\
 &= - \frac{1}{s} \cdot \frac{r}{I}
 \end{aligned}$$

FIGURE 2

where s is the slope of the function at the relevant (I, r) at which the elasticity is being investigated; for a linear marginal efficiency function the slope is the same throughout. Since at every level of the interest rate I_{M_1} is less than I_M while the slopes of M_1M_1 and MM are identical, the elasticity of M_1M_1 exceeds that of MM ; the risk allowance everywhere *increases* the interest elasticity of investment.

Case 2. The risk allowance is different among projects but is independent of the unadjusted yields.

Following Tarshis, again let MM in Figure 2 represent the marginal efficiency function, unadjusted for risk allowances, and draw the functions M_1 and M_2 "so they lie A per cent and $(100-A)$ per cent respectively of the horizontal distance from the vertical axis and MM . Then M_1 is the marginal

efficiency function comprising projects on which a risk allowance of b is to be levied; M_2 is the corresponding function for projects on which the allowance is to be c " [3, p. 972]. Thus m_1 is drawn b percentage points below M_2 , m_2 is c percentage points below M_2 , and the horizontal sum of these two is given by M_A . Since at every level of the interest rate below the kink, K , the slopes of M_A and MM are the same whereas the corresponding amount of investment I_A is less than I_M , it follows that the elasticity of M_A exceeds that of MM . Below the kink, therefore, the effect of the risk allowance is again to *increase* the interest elasticity of investment.

Case 3. The risk allowance is proportional to the yield on the projects.

FIGURE 3

Here both the slopes of the functions and the magnitudes of the investments are so affected by the risk allowance that the latter results in an *increase* in elasticity at every interest rate.¹ That is, the absolute slope of M_1M_1 in Figure 3 is less than that of MM while at every level of the interest rate I_{M_1} is less than I_M . The increase in elasticity follows directly.

Combining the Tarshis function with our own we obtain the following nonlinear marginal efficiency expression:

$$I = \alpha_0 - \alpha_1 r + \alpha_2 r^{-\beta}$$

where each of the parameters is nonnegative. For $\alpha_0 = \alpha_1 = 0$ we have the Tarshis hyperbolic relation; for $\alpha_2 = 0$ we have our linear one. Assuming positive values for each parameter, the same three cases considered above provide results somewhere between those obtained by Tarshis and those developed by us. Thus for Cases 1 and 2 the introduction of a risk allowance may produce an adjusted function which is either more or less elastic than the unadjusted one. The outcome simply cannot be determined a priori. However, Case 3 provides us with a condition where the risk allowance unambiguously produces an adjusted function which is more elastic than the unadjusted one. In the absence of specific numerical estimates of the parameters, Cases 1 and 2 yield a mixed result while Case 3 is flatly contradictory to the usual view. Since this combined expression appears to be quite general indeed, it raises grave doubts concerning the standard arguments that the risk allowance necessarily transforms what might otherwise be an elastic function into an inelastic one.² Indeed it is entirely possible that the effect may go the other way.

The Elasticity of the Marginal Efficiency Function: Comment

In "The Elasticity of the Marginal Efficiency Function,"¹ Lorie Tarshis analyzes the widely-held view that investment projects involving long-lived capital are more responsive to changes in the interest rate than projects involving short-lived capital. He cites the supporting argument that "when projects are short-lived, . . . a change in the interest rate will . . . make little difference to costs" because "interest charges are relatively low" and "the ratio of depreciation allowances to interest is relatively high," while when projects are long-lived the opposite is true (p. 962). But, on the basis of four comparisons of hypothetical short-lived and long-lived projects, he concludes that "while these statements may be perfectly correct it is doubtful whether . . . they cast any light at all upon the elasticity of the marginal efficiency function."

The purposes of this comment are (1) to point out a defect in the method of analysis employed by Tarshis, (2) to present an analysis, free from that defect, which supports the view that the marginal efficiency function for longer-lived capital projects does have greater elasticity, and (3) to show that the factor affecting the elasticity of the marginal efficiency function may be described in more general terms as the capital-sales ratio rather than the length of life of the capital asset.

My criticism of Tarshis's method is, briefly, this: In three of his four hypothetical comparisons he has, in effect, drawn two identical marginal-efficiency-of-capital curves (that is, curves whose elasticities are the same by assumption), labeling one "Short-Lived Projects" and the other "Long-Lived Projects," and has then proceeded to demonstrate that the elasticity of the second marginal efficiency function is no higher than that of the first. This, surely, is an illegitimate procedure. Since the two functions have been made identical by hypothesis, it has been made impossible to reach any other conclusion. If equality of elasticities is to be *demonstrated*, it must not be *assumed*.

There is, it is true, a troublesome methodological problem which has to be faced, as Tarshis points out. In order to examine the relation between the length of life of projects and the elasticity of the function, "we must specify a model in which, while the length of life of the assets is made to vary, all other aspects of the projects are held constant" (p. 962). But if some "other aspects" are held constant, others must necessarily vary. Tarshis therefore makes four alternative assumptions about what is to be held constant (p. 962): (1) the "pattern of expected yields," or, the same thing, "the pattern of specific marginal efficiencies"; (2) the "pattern of expected 'increments' or Q 's," the Q 's in each case being the project's annual receipts gross of depreciation and interest but net of other costs; (3) the "pattern of Q 's adjusted for differences in depreciation allowances" so as to make "the patterns of the annual contributions to net profit . . . the same" (p. 966); and (4) the pattern of marginal efficiencies (as in No. 1), it now being assumed,

¹ This *Review*, Dec. 1961, 51, 958-85.

however, that there are "induced changes in the prices of capital goods" which can change the pattern.

Clearly No. 1 is an inadmissible assumption; it assumes away any possibility of difference in elasticities and thus prevents any meaningful inquiry into the effect of longevity on the marginal efficiency function. No. 3 turns out to be nothing more than a disguised form of No. 1; to assume that "the patterns of the annual contributions to net profit" are the same is equivalent to assuming that the patterns of marginal efficiencies are the same (see Table 4, p. 966).² Again, that which was to be demonstrated has been made true by assumption. No. 4 has the same basic defect; it restricts the inquiry to the question, "If the elasticities are alike for short-lived and long-lived projects when the prices of capital goods remain constant, will they continue to be alike if variations in investment demand cause capital goods prices to vary?" It, too, therefore, prevents the main question from being investigated. Only Assumption No. 2 is free from this methodological defect—and when that assumption is made Tarshis shows that "the elasticity of the marginal efficiency function will be higher when projects have a longer life" (p. 965).

Is Tarshis' second interpretation of the *ceteris paribus* assumption, then,

² This fact is somewhat obscured by Tarshis' use of the discounted-present-value formula to find the "annual increment" (*Q*) corresponding to any given yield for a project of stated life and stated supply price. By doing so, and by assuming straight-line depreciation (which is not in accord with the diminishing series of recoveries of capital obtained by the discounted-present-value formula), he obtains a pattern of "annual net profits" for his short-lived projects which differs very slightly from the pattern of yields from which it is derived. This can be seen from Table 1 (based on Tarshis' Tables 2 and 3).

TABLE 1—EXPECTED YIELDS AND PROFITS FROM SHORT-LIVED PROJECTS

Project	Annual Increments	Yield (Per Cent)	Index of Yields	Annual Depreciation	Annual Net Profit	Index of Net Profits
A ₁	\$224.63	4	100	\$200	\$24.63	100
B ₁	\$230.97	5	125	\$200	\$30.97	125.74
C ₁	\$237.40	6	150	\$200	\$37.40	151.85
D ₁	\$243.89	7	175	\$200	\$43.89	178.20

If the annual increments are computed instead by the method I have used later in this comment, not only does the arithmetic become simpler—the four annual increments become exactly \$224, \$230, \$236, and \$242—but the index of net profits becomes 100, 125, 150, and 175, coinciding exactly with the index of yields. This alternative method of computation seems to me conceptually more satisfactory; no longer does the puzzling situation exist in which the annual net profit on Project A₁, \$2.63, is 4 per cent of \$615.75 (which, by implication, must be the average amount of capital invested) while the annual net profit on Project D, \$43.89, is 7 per cent of \$627.00 (implying a higher average quantity of capital tied up although the initial investment is the same in both cases).

If Tarshis' Tables 3, 4, and 5 were revised to conform to my method of computing annual increments and annual net profits, it would become clear that what he has done is, in essence, to start with a 4:5:6:7 pattern of yields for short-lived projects, resulting in a 4:5:6:7 pattern of annual net profits. He has then adjusted the annual net profits of the long-lived projects in order to make their ratios 4:5:6:7. When the \$200 depreciation is added to each net profit of the long-lived projects, the resulting set of annual increments must necessarily represent yields of 4, 5, 6, and 7 per cent.

the correct interpretation? I think it is. To obtain a clearer view of this question, let us examine a slightly modified version of Tarshis' model.

Assume four short-lived projects (A_1, B_1, C_1, D_1), each requiring an initial investment of \$1000 and having a life of five years. Each project is to be financed with borrowed money, the loan being paid off in yearly installments. On the average, then, the size of the loan outstanding is \$600^a and the annual depreciation and interest charges are:

$$.2S + .6rS; \text{ or } \$200 + r(\$600)$$

where S represents the supply price of the project and r the interest rate (or, alternatively, the marginal efficiency when the expression above is equal to the project's annual Q). Assume, as Tarshis does, that these short-lived projects promise yields of 4, 5, 6, and 7 per cent respectively. Then their annual receipts (Q 's) are \$224, \$230, \$236, and \$242 respectively.

Assume also four long-lived projects (A_2, B_2, C_2, D_2), each having a life of ten years; assume that *when the interest rate on loans is 5 per cent*, each of the long-lived projects would have the same annual depreciation-and-interest costs as would each of the short-lived projects at that interest rate (namely \$230); and assume that each is expected to bring in the same stream of receipts as its corresponding short-term project—that is, \$224, \$230, \$236, and \$242 respectively.

On these assumptions, the depreciation-and-interest cost of each of the ten-year projects must be:

$$.1S + .55rS$$

and the supply price of each ten-year project must be \$1803.92. The marginal efficiencies of the eight projects must then be as shown in Table 2. It is seen that the elasticities are greater for the set of projects with ten-year lives.

TABLE 2—EXPECTED YIELDS FROM SHORT-LIVED AND LONG-LIVED PROJECTS

Short-Lived Projects				Long-Lived Projects			
Project	Annual Receipts	Annual Depreciation	Yield (Per Cent)	Project	Annual Receipts	Annual Depreciation	Yield (Per Cent)
A_1	\$224	\$200	4	A_2	\$224	\$180.39	4.4 ^a
B_1	\$230	\$200	5	B_2	\$230	\$180.39	5.0
C_1	\$236	\$200	6	C_2	\$236	\$180.39	5.6 ^a
D_1	\$242	\$200	7	D_2	\$242	\$180.39	6.2 ^a

^a Approximate figures.

The crucial question, of course, is: Are there solid grounds for assuming that the two patterns of annual receipts are the same? I think it can be shown that there are—if certain other assumptions are accepted as reasonable. First, let us think of the economy's array of projects, represented by the eight projects shown in Table 2, as investment possibilities in as many dif-

^a If an individual had five such projects in operation, begun in successive years, his debt capital would remain constant at \$3000.

ferent markets or industries, it being assumed that in each market or industry only the most profitable of the not-yet-undertaken projects is under consideration.⁴ Second, let us abstract from economies of scale and the indivisibility of durable capital assets, so that in any industry the yield of the marginal project not yet undertaken does not differ appreciably from the yield of the marginal capital already invested.⁵ And third, let us think of the economy in question as a competitive economy whose long-run equilibrium position would require a Wicksellian natural rate of interest of 5 per cent. If this economy were in long-run general equilibrium, all eight projects would be equally marginal and would have to produce annual receipts of \$230. The fact that some projects in Table 2 (when interpreted in this manner) have higher yields than others simply indicates that some industries offer more attractive investment opportunities than others and reveals a situation of long-run disequilibrium, caused by such things as recent changes in tastes, imperfect knowledge, and technological change. Any difference between a project's expected stream of receipts and its long-run equilibrium stream, \$230, must be due to the fact that productive capacity in the market that

* At first thought this may seem to be an unwarranted limitation; yet to assume otherwise would get us into a quagmire of difficulties. Consider the possible reasons why hypothetical projects in the same industry and geographical market might differ in prospective yield. (1) Two projects involving the sale of identical products may call for different methods of production—and therefore have different costs. But in this case the inferior project should not be in the array, for we should assume that investors act like economic men and, when a choice of production methods is possible, rule out any method which does not minimize costs. Moreover, if we were to admit into the array projects characterized by unnecessarily costly methods, the number of such projects would be limitless and the elasticity of the marginal efficiency functions for both short-lived and long-lived projects would become indefinitely large. (2) The products to be produced may differ in quality, resulting in differences in cost and/or revenue schedules which make one project less profitable than the other. But rational investors should refuse to consider a project which calls for the sale of a product of unnecessarily inferior or unattractive quality. And in this case also, meaningful analysis of the marginal efficiency function becomes impossible if we admit into the array the infinite number of conceivable projects in each industry made possible by continuous variation in quality. (3) Barring differences in production functions and in product quality, projects within the same industry and geographical market become economically indistinguishable and can be assigned different prospective yields only if they are interpreted to represent successive injections of new capital into the industry. This, of course, might be done. That is, we might suppose that Projects A and B are identical twins and Project B's yield is lower than Project A's only because it is calculated on the assumption that Project A has already become a reality. But this interpretation of the marginal efficiency function is inconsistent with the concept of the function as an aggregation of many individual projects which individual businessmen have in mind at some given time. Moreover, even if it were adopted, the conclusions reached in the argument that follows would be unaffected since the elasticity of the curves showing the yield of successive doses of homogeneous new investment in an industry depends on factors which are totally independent of the length of life of the durable capital required: namely, the elasticity of demand for the industry's product and also, in cases where subsequent investments entail higher costs because of the necessity of selecting poorer locations or making use of inferior or more costly labor and natural resources, on the elasticity of supply of labor and natural-resource inputs.

⁵ This assumption does not imply an unrealistic world in which one-room hotels are as efficient as large hotels; it merely implies that existing hotels may be expanded one room at a time—and will be if expansion on a larger scale would lower appreciably the marginal rate of return on capital in the hotel industry.

would be served by the project is out of line with current demand, causing the price in that market to differ from the long-run equilibrium price. Disequilibrium in each case must have been caused by a change in demand or a change in the cost schedule.

Is there any reason to expect the percentage deviations from long-run equilibrium price to be greater in the case of markets served by long-lived projects than in markets served by short-lived projects? They would be greater only if the disequilibrating shifts in demand or cost schedules that had caused them tended to be greater in the former markets. There would be no reason to expect changes in demand to be greater, since they stem from causes that are completely independent of conditions of supply. Nor would changes in labor costs, land costs, or costs of materials and services supplied by other firms be greater, since these too stem from causes that are unrelated to the length of life of the capital equipment. The only sort of change that could possibly be expected to cause the cost schedule to vary more widely in the case of long-lived projects is a change in the project's supply price (or the inverse, its quality). But even here the length of life of the project makes no difference. Suppose, for example, that the supply prices of B_1 and B_2 are reduced by 10 per cent, the interest rate of loans being fixed at 5 per cent. In both cases the depreciation-plus-interest cost falls from \$230 to \$207.⁶ In both cases the annual receipts—and the market price of the product that brings in the receipts—are higher than their new long-run equilibrium value by the same per cent. On the other hand, the marginal efficiencies of the two projects have risen unequally. The yield of B_1 has risen from 5 to approximately 9.3 per cent, while that of B_2 has risen to only approximately 7.6 per cent. Thus we must conclude that, on theoretical grounds, there is no reason to assume any difference in the dispersion of the Q 's of short-lived and long-lived projects—and therefore there *is* reason to assume that the patterns of yields are *not* alike.

The argument can be reinforced by taking a pair of extreme cases. Asset E_1 has only a one-year life; asset E_2 has an infinitely long life. Assume that in both cases the long-run-equilibrium stream of receipts, representing a 5 per cent rate of return over cost, is \$230. Since the entire supply price of E_1 must be recovered each year, the allocation of receipts to depreciation and interest must be $S + .05S$; the supply price, then, must be \$219.05, and the interest cost, at 5 per cent, \$10.95. In the case of E_2 , depreciation being nil, the entire \$230 represents the annual return on the invested capital, $.05S$, and S must be \$4,600.

Now consider the effect of a fall in the interest rate from 5 to 4.5 per cent. In the case of E_1 , the annual depreciation-and-interest cost will fall from \$230 to \$228.91—a reduction of less than $\frac{1}{2}$ of 1 per cent. In the case of E_2 , the annual cost will fall to \$207—a reduction of 10 per cent. If the expected receipts in both cases were, say, \$220 plus or minus 5 per cent, project E_1 would remain an extremely poor risk while project E_2 would

⁶ In the case of the five-year project it falls from $200 + 30$ to $180 + 27$ dollars. In the case of the ten-year project it falls from $180.39 + 49.61$ to $162.35 + 44.65$ dollars.

become a certain success. The long-lived project is much more sensitive to changes in the interest rate.

A broader question is now worth asking. Must the factor affecting the elasticity of the marginal efficiency function be identified, as has been done so far in this comment, as the length of life of the fixed capital? Or can it be described in more general terms? A little reflection will show, I think, that the reason for the greater elasticity of the marginal efficiency function for longer-lived projects is the fact that the ratio of the supply price (S) to the expected net receipts (Q) associated with any given yield is higher. This ratio can vary for only one reason: variation in the longevity of the capital. But there is another ratio—that of the supply price to the expected *gross* receipts associated with any given yield—which can vary among projects which have the same length of life. And it can be shown that when this ratio becomes higher the elasticity of the marginal efficiency function becomes greater.

In my argument in support of the assumption that the patterns of receipts are alike for short-lived and long-lived projects, I assumed implicitly that if the patterns of gross receipts from sales were alike for both types of projects, the patterns of Q 's (receipts gross of depreciation and interest but net of other costs) would be alike. Actually this would be the case only if "other costs" were in all cases the same percentage of gross receipts. For the purposes of my analysis it was not only satisfactory but necessary to assume that they were (in order to prevent an irrelevant variable, which should be chained down by the *ceteris paribus* assumption, from muddying the analysis). Yet in reality the ratio of depreciation-and-interest cost to total cost varies among projects. And this variability affects the ratio of invested capital to gross annual receipts, which may be termed the *capital-sales ratio*.

Let us see what happens when this ratio differs between two sets of equally long-lived projects. Assume that projects A_1 , B_1 , C_1 , and D_1 are such that each entails an initial capital investment of \$1,000 and annual labor costs of \$200, while projects A_2 , B_2 , C_2 , and D_2 are such that each entails an equally high initial capital investment, \$1,000, but annual labor costs of only \$100. All eight projects have five-year lives. To keep matters simple, assume that working capital is not needed and that each project is a completely vertically-integrated production scheme, so that no intermediate products have to be purchased. With an interest rate of 5 per cent, the annual costs of each *low-capital-sales-ratio* project ($A_1 \dots D_1$) are \$430 while the annual costs of each *high-capital-sales-ratio* project ($A_2 \dots D_2$) are \$330. Now, if we assume the same pattern of gross receipts for both types of projects (that is, the same corresponding percentage deviations from the zero-profit level of gross receipts at an interest rate, say, of 5 per cent), the percentage deviations of *net* receipts (after deducting labor costs) will not be the same; they will be smaller for the projects having the higher capital-sales ratios. This being so, the marginal efficiencies of the high-capital-sales-ratio projects will lie within a smaller range than those of the low-capital-sales-ratio projects. Therefore the marginal efficiency function of the projects having the higher capital-sales ratios will have the higher elasticities.

According to this analysis, the elasticity of the marginal efficiency function is an increasing function of the capital-sales ratio. The capital-sales ratio, in turn, is an increasing function of (a) the length of life of the capital asset—or, the same thing, the ratio of interest cost to depreciation cost for any given interest rate—and (b) the ratio of depreciation-and-interest cost to total cost. This conclusion may be restated in more straightforward terms as follows: the higher the initial cost of an investment project relative to annual receipts from sales, the higher will be the interest cost relative to receipts from sales, and the smaller will be the change in the interest rate needed to make any given unprofitable project profitable.

The Elasticity of the Marginal Efficiency Function: Reply

Williamson has been able to derive somewhat more general results about the consequences, for the elasticity of the marginal efficiency function, of an increase in the riskiness of investment projects. He shows that they depend not only upon the nature of the allowances to be made for risk but also upon the characteristics of the function unadjusted for risk.

His results can be extended a little further, though the extension does not reduce at all the need for empirical investigation. This extension can be illustrated by considering one set of risk allowances—that in which the expected yield on each project is reduced by the same absolute number of percentage points.

When the unadjusted function is iso-elastic, as I assumed initially (pp. 969-77), it becomes less elastic at each interest rate. Williamson shows that when the unadjusted function is linear, and its elasticity is then higher at low levels of investment than at higher, it becomes more elastic at any interest rate as a result of making the appropriate risk allowances. Clearly, as he states, there must be a function, somewhere between his and mine, for which elasticity falls just fast enough with increases in investment to keep the elasticity of the adjusted function equal to that of the unadjusted function at each interest rate. Then for any unadjusted function for which the rate of decline in elasticity with higher investment exceeds the norm, the adjusted function will be more elastic at each interest rate than the unadjusted; and vice versa if the rate of decline is less than this.

The characteristic required of the unadjusted function in order that there be no change in elasticity as the result of making the specified allowances for risk, is this: Let r_1 be the interest rate, and b be the allowance for risk on each project. Then the ratio of the elasticity of the unadjusted function at a rate of interest $(r_1 + b)$ to its elasticity at r_1 must be equal to the ratio

$$\frac{r_1 + b}{r_1}.$$

Or, to illustrate it numerically, if the interest rate is 6 per cent and the allowance for risk is uniformly 12 per cent, the elasticity of the unadjusted function at 18 per cent must be three ($= 18\%$) times as high as it is at 6 per cent.

Whether this condition is likely to be realized or not is something that to my mind defies a guess. It appears stringent, but actually with a linear function the ratio of the elasticity is greater than it need be to meet this condition, and in the absence of empirical knowledge it can hardly be dismissed as an impossible or even unlikely condition.

As Abbott points out, we cannot be surprised to find that the elasticity of the function is the same whether projects are short-lived or long-lived, when the notion of *ceteris paribus* is understood to mean either that (1) the patterns of specific marginal efficiencies or (2) the patterns of Q 's adjusted for differences in depreciation allowances are the same, since each interpretation amounts to the assumption of identical functions. Whether the procedure is illegitimate, as he asserts, is however a question that depends upon the marital state of the parents. I thought that the hoary respectability of the conventional arguments would legitimize my procedures since the latter stemmed from these arguments and tried to answer them; for these arguments are usually set out as though the content of the *ceteris paribus* assumption made no difference whatsoever. I am ready to agree that if the usual arguments had not been persuasive to some (other than myself) then I ought not to have assumed what I was intent on demonstrating. But were they not?

Abbott finds as I did (p. 965) that when the patterns of expected increments or Q 's, the Q 's in each case being the project's annual "receipts gross of depreciation and interest but net of other costs," are the same, the elasticity of the function will be higher when projects have a longer life. And the burden of his comments is to assert that this is "*the* correct interpretation" of the *ceteris paribus* notion.

His argument is strong, though I am not convinced that it is complete or that it necessarily applies in the context in which the main point is commonly made—that the response of investment in, say, residential construction and other very durable assets to a change in interest rates will be greater than for investment in short-lived equipment and inventories.

He rests his argument upon the notion that when differences in prospective yields exist, this reveals a situation of long-run disequilibrium (see also my original paper, pp. 983-84). Looking at the sources of such a disequilibrium (say, changes in demand or costs) he can find no reason for supposing that their effects upon the patterns of Q 's for long-lived projects would differ from their effects upon the comparable pattern for short-lived projects.¹ Hence it follows that the patterns of the Q 's would be no different, and so on. But there

¹ I believe he has made his own argument, however, unduly restrictive, for one thing, by seeking to limit the number of projects in the array. He is surely incorrect in asserting, as he does in his footnote 4, that when the number of projects is limitless the elasticity of the marginal efficiency function becomes indefinitely large. He has presumably failed to notice that it is the *relative* change, and not the absolute change, in investment that matters.

is at least one reason which rests upon differences in durability for expecting a disequilibrating change to affect the patterns of Q 's in different ways.

Suppose that changes in wage rates (or technology) have been occurring over recent years. Since the less durable assets will, on the average, be the younger, we may reasonably expect them to be more nearly appropriate at a given date to current and prospective wage rates (or the state of technology) than are the older or more durable assets. From this it would follow that their replacements would show a *smaller* differential advantage over those that become due for retirement than is true of the advantage of the replacements for the more durable assets over those these latter are to replace. Then, the pattern of Q 's for long-lived assets will tend to be *more* dispersed than the comparable pattern for short-lived assets, and the elasticity of the marginal efficiency function for the long-lived assets could easily be lower.

Or, supporting Abbott's view, it could be argued that the sponsors of long-lived projects would normally tend to make their estimates of the Q 's on the basis of the relatively stable parameters, discounting more ephemeral developments, while those concerned with the shorter-lived projects would have to concern themselves much more with the day-to-day changes. If this were so, the elasticity of the function for long-lived projects would tend to be higher.

Once again, though, it seems that we dare not *reason* our way to a firm conclusion. Abbott may be correct in holding that the developments which create long-run disequilibria may modify the patterns of the Q 's for long-run and short-run projects in the same way, but his argument rests again upon giving to the *ceteris paribus* notion a special meaning. And I would instead prefer to be guided by what, if anything, the facts disclose.

Foreign Exchange Guarantees and the Dollar: Comment

In the June 1961 issue of the *Review*, S. T. Beza and Gardner Patterson express doubts about the value of exchange guarantees [1]. Their first argument is that, if the guarantees are credible, "a system of exchange guarantees whose major *raison d'être* appears to be to protect our gold stock ends up by greatly reducing its usefulness for international reserve purposes" [1, p. 383]. Their second argument is that, if the guarantees are "to prove not credible, then, to institute the system would be a disaster, for it would fail in its purpose, cost us real goods and services if implemented, and, if abandoned, would be a signal for new runs" [1, p. 385].

Beza and Patterson correctly recognize that exchange guarantees would be difficult to negotiate and they might not be universally applicable. Problems would arise in constructing fences between the dollar holdings subject to the guarantee and other dollar holdings. It is necessary to distinguish those particular foreign holders eligible for the guarantee from those who are not eligible, to distinguish those dollar assets held by eligible holders subject to the guarantee from their other dollar assets, to define unambiguous conditions for

determining when the guarantee would be invoked, and to determine how payment under the guarantee would be effected. Moreover, it is important to anticipate, as Beza and Patterson do, the measures that would have to be taken if, sometime after a country received payment on a guarantee, it devalued its currency by an amount proportional to the devaluation of the dollar, or by a greater, or lesser, amount.

Despite these real problems, there are situations in which exchange guarantees might prove useful, and it would be unfortunate if the case presented by Beza and Patterson detracted attention from their merits. By considering only two extreme situations, one where a guarantee is fully credible and a second where it loses its credibility, Beza and Patterson have failed to acknowledge the major arguments for the guarantee.

I. The Beza and Patterson Analysis Reviewed

Their first point is that, if the guarantees are credible, dollars would become such an attractive reserve asset that few official foreign institutions would acquire or hold gold as reserves, with the consequence that the United States might again be subject to a golden avalanche. Gold apparently would become increasingly useless to the United States simply because foreign official institutions, content with the guarantees, would not seek to convert their holdings of dollar assets into gold.

This view appears to presuppose that the United States could run payments deficits forever because foreigners would be perfectly willing to accumulate dollar assets ad infinitum.¹ By giving the guarantee, the United States would never need to devalue because of a shortage of acceptable assets for financing a deficit. It is true that the United States would have to pay interest on a larger volume of dollar assets held by foreigners, but U.S. interest rates might be lower than in the absence of a guarantee because there would be no need to pursue an interest-rate policy designed to protect the U.S. gold reserve.

But is it really possible that, merely by giving the guarantee, the United States would be forever immune from the discipline of the balance of payments? That foreigners would look with equanimity on the growth of U.S. short-term liabilities to foreigners many times that of the U.S. gold stock? The assumption (which they themselves characterize as "heroic") that a guarantee can be fully credible independently of the U.S. net reserve and balance-of-payments position, removes any problem of significance so that the conclusions based on this assumption are irrelevant.

A guarantee might lose its credibility if the suspicion were to arise that the United States might not be willing to honor the guarantee after a devaluation. The most likely basis for doubt about the credibility of the guarantees is a high cost of honoring it, a cost which, as Beza and Patterson emphasize, might become exceedingly large if it is impossible to build a tight fence between

¹ In this never-never world, the United States nevertheless still might want to devalue if maintaining an overvalued exchange rate had undesirable deflationary consequences for the United States. Whether the guarantees would then be costly to the Treasury would depend on whether the amount of the dollars subject to guarantees exceeded the additional amount of gold acquired by the United States as a result of the guarantee.

foreign-owned dollar assets which we wish to guarantee and other foreign-owned dollar assets.

Two points should be noted: First, part or all of the direct financial cost of honoring the guarantees could be met from the revaluation profits on the U.S.-owned gold. These profits would accrue on all the U.S.-owned gold, while only a part of the dollar assets held by foreigners would be eligible for payment under the guarantee. Today only two-thirds of the short-term dollar assets held by foreigners are in the hands of official foreign institutions. If other countries devalued along with the United States, they would not be eligible for payment under the guarantee.

Second, the financial burden of honoring the guarantee would only become translated into a real burden on the United States, in the sense that it would have to transfer a larger volume of goods and services to foreigners, if foreigners were to incur larger payments deficits with the United States because of the larger dollar value of their reserves.² This may, of course, happen, but the outcome remains conjectural. The value of their reserves in terms of their home currency remains unchanged, even if it increases in terms of dollars. It does not follow that the devaluation will mean that the countries who benefit under the guarantee are likely to have their payments balance shift from a surplus to a deficit.

If the net impact of the U.S. devaluation is to achieve a balance in the U.S. external accounts, the financial cost of honoring the guarantee is not likely to have a significant counterpart in terms of a real cost to the United States because the latter would have to make available a larger volume of goods and services to foreigners. There may be a foregone gain, however, since foreigners might feel a lesser need to build up their dollar reserves, so that the United States would not be able to run payments deficits in the future, and acquire unrequited goods and services, to the extent that it would otherwise be able to.

The problem of the real costs involved in honoring the guarantee cannot be divorced from the impact of the guarantee. To the extent foreign official institutions accept the guarantee at its face value, the United States will be able to run a larger payments deficit. When and if the United States subsequently devalues, it will be subject to an adverse change in its terms of trade; this increase in U.S. import prices relative to U.S. export prices will result in a decline in U.S. income. This is the real burden of the devaluation, separate and apart from any real burden of the guarantee. But to the extent that the guarantee enables the United States to delay the devaluation, it will delay also the adverse shift in the terms of trade with its concomitant loss of real income.

Whether the real burden of honoring the guarantee will exceed the saving in real income from delaying the adverse shift in terms of trade is conjectural. It is quite possible that the real burden may be less than the forestalled de-

² There may be a real burden on the United States even if there is no financial burden, i.e., even if the U.S. gold revaluation profits are more than adequate to cover the cost of honoring the guarantee.

cline in real income; in any event the issue is far more complicated than Beza and Patterson make it.

II. *Arguments for Guarantees*

An exchange guarantee appears advantageous for a number of reasons. First, a change at the margin, in the reserve-holding preference between dollars and gold might enable the United States to run a larger payments deficit than it is now able to, given the present U.S. gold reserves. A guarantee thus becomes a device for increasing reserves and international liquidity. A guarantee does not have to be fully credible to achieve this result. (Whether the United States should be in a position to run a larger deficit is a different matter, although the continuation of the present payments imbalances and the intractability of the deficits and surpluses suggest that more reserves may be needed to give time for adjustment.)

But even if the guarantee were not at all effective in altering the preferences of foreigners for holding gold or dollars, the guarantee may still be effective in situations in which the dollar-gold parity is appropriate but in which a run on the dollar by private individuals would, in the absence of the guarantee, ignite a run on gold by official foreign institutions. Such a flight into gold might force the United States to suspend gold convertibility. While no foreign central bank wishes to cause such a calamity, it does feel an obligation to its own stockholders. Each of the foreign central banks, acting independently to protect its immediate and obvious interests, would contribute to fracturing the system. No one wishes such a result, but individually each country is relatively defenseless against it.

Another argument for the guarantee is that it becomes somewhat of a barrier against retaliatory devaluations; foreign central banks holding guaranteed dollar assets would be deprived of the chance to use the capital loss on their holdings of dollar assets as an excuse for a countering devaluation. In this case the guarantee may be a necessary element in achieving a successful devaluation of the dollar should it become clearly overvalued; the guarantee limits similar devaluations by other countries. Beza and Patterson emphasize the other side of this coin—that because of the cost of honoring the guarantee, the United States might not devalue when economic circumstances suggest that it should.

Joining the issue at this level involves several imponderables. The issue is quite clear—it is whether the financial cost of a devaluation, in the sense of the loss on the home-currency value of foreign-owned dollar assets, will be assumed by the foreign country, or made good by an exchange guarantee.³ While Beza and Patterson acknowledge that the financial cost of honoring the guarantee may prevent the United States from devaluing, they fail to acknowledge that the financial cost otherwise borne by other countries may force a retaliatory devaluation, in which case the devaluation of the dollar would be unsuccessful. It is, of course, possible that some foreign countries

³ If a guarantee had been arranged, it is still not clear that the cost of making good the loss to foreigners would exceed the gold revaluation gains of the United States.

might grudgingly take the capital loss, rather than devalue to avoid taking a capital loss.

Finally, certain matters of equity would become important following any change in the gold parity of the dollar. In the nature of things, the likelihood of the devaluation must be denied until it occurs. But if it does occur, then the U.S. Treasury will be the beneficiary of revaluation profits on its holdings of gold and foreign currencies, and private U.S. investors will secure capital gains on their foreign investments, while foreigners will suffer losses on their holdings of dollar assets. Politically it may be exceedingly embarrassing to take such revaluation profits, while causing foreigners to take revaluation losses. In such circumstances, compensation might be in order; part of the U.S. revaluation gains might be transferred to foreign official institutions to offset their loss.⁴

III. Conclusion

The critical issue appears to be whether the advantages of the guarantees exceed their costs. These costs are the real costs that would fall upon the United States if it devalues and chooses to honor the guarantees, in excess of the costs that it might bear if, in the absence of a guarantee, it devalued and nevertheless chose to make compensatory payments in view of its pledges. The advantages of the guarantees, aside from the equity consideration noted earlier, include the increased flexibility available to the United States in financing larger payments deficits than are otherwise possible, and in thus increasing international liquidity, and the increased cohesiveness it gives the payments system against a breakdown that might ensue if most holders of dollar assets sought to convert them to gold at the same time. Whether the advantages outweigh the costs is essentially an empirical matter not easily given to measurement. Few advocates of guarantees claim that their adoption solves all the problems encountered in achieving a stable international payments system, and yet their possible contribution to such a system cannot be overlooked.⁵

*The author is on the research staff of the Committee for Economic Development. The views in this comment are not necessarily those of C.E.D. or of any of its subcommittees. He is indebted to Frances K. Topping for numerous editorial suggestions.

⁴It can be argued that it is preferable to arrange compensation after a devaluation rather than before, since this eases the problem of negotiating, and the amount of compensation can be tailored to the U.S. gold revaluation profits. But if one does feel that this equity problem is important, and that the United States should honor the statements made by various public officials indicating that the dollar price of gold would remain unchanged, it would seem advantageous to obtain the benefits of a guarantee if one is going to bear the costs.

⁵Most advocates of guarantees favor their adoption as part of major reform of the international financial system, and it is hard to see how any such reform could be negotiated without including guarantees. Yet guarantees may be useful even in the absence of such reform.

Foreign Exchange Guarantees and the Dollar: Reply

Aliber's "Comment" contains several interesting points and we welcome this additional discussion of an important question. We are pleased to find that he agrees with one of our major conclusions—that exchange guarantees are not a simple device—and he is no doubt correct when he says that some of the issues are "far more complicated" than we suggested.

There are a few important points in his comment with which we disagree and it is only these that we will discuss here. His first criticism of our note seems to rest on his assertion that our view that a credible guarantee would greatly reduce the usefulness of gold for international reserve purposes "... appears to presuppose that [with a credible guarantee] the United States could run payments deficits forever because foreigners would be perfectly willing to accumulate dollar assets *ad infinitum*." We presuppose nothing of the kind. What we do say is that with a credible guarantee gold becomes inferior to the dollar, and that countries choosing between *these two* as international assets will opt for the dollar. This does not imply that the dollar becomes impregnable. Foreigners accumulating foreign exchange, whether dollars or gold or something else, are performing an act of saving, and the rest of the world in any one time period may choose to save more or less than in the past, and it may elect to alter the form in which its savings are invested. A decision by the rest of the world to save more in the form of, say, steel mills and less in foreign exchange holdings, or a decision to increase consumption may be sufficient to erase a United States balance-of-payments deficit. That foreigners may decide to stop adding to their dollar holdings in favor of some other form of investment, irrespective of the existence of exchange guarantees, should be obvious.

Aliber states that we have failed to acknowledge the major arguments for an exchange guarantee. This may be correct, but the evidence he advances for this view is not overwhelming. The first reason he puts forth for guarantees is that they "might enable the United States to run a larger payments deficit than it is now able to. . . ." Exactly; we differ only in that we stated it as "increasing the amount we could borrow at any one time on short term from abroad. . . ." Further, we agree with his argument that a guarantee need not be "fully" credible to achieve this end; it is a matter of changing preferences, at the margin, among possible reserve assets. More generally, in presenting our discussion in terms of the two extremes we may have ignored some of the advantages as well as some of the difficulties associated with exchange guarantees. His argument that guarantees offer some barrier against retaliatory devaluation has some merit, but we see no reason, especially with the existence of the International Monetary Fund, for considering seriously "competitive devaluations" as a problem now or in the future.

Aliber's argument for guarantees based on equity considerations requires more space than is available here. Equity considerations are important. We would suggest, however, that there is little evidence that devaluing countries, including major reserve centers, have found it politically embarrassing to take unto themselves fully the devaluation "profits."

In his conclusion, Aliber appears to adopt the view that compensation should be paid to foreign holders of dollars in the event that the dollar is devalued. He states that the real cost of an exchange guarantee is the excess of the "real costs that would fall upon the United States if it devalues and chooses to honor the guarantees" over the "costs that it might bear if in the absence of a guarantee it devalued and nevertheless chose to make compensatory payments in view of its pledges." Is this a useful way in which to view the choices available? We fail to see why, in the absence of guarantees, the United States would "nevertheless choose to make compensatory payments." The United States has been a generous nation, but would this not be considered going too far?

Stochastic Reserve Losses and Expansion of Bank Credit: Comment

Orr and Mellon present in a recent issue of this journal an analysis of expansion of bank credit that introduces uncertainty into the model of bank decision-making [1]. Unfortunately, certain aspects of their model and discussion of it are subject to criticism. The one that stands out most clearly, perhaps, is that their results depend upon the assumption that the return on funds that are lent out or invested does not exceed the charge a bank incurs when it borrows funds to cover losses.

Orr and Mellon's analysis makes use of the following variables and parameters: R , excess reserves acquired by the bank at the beginning of the period; D , deposits created by the bank; L , the loss of reserves the bank suffers during the period; i , the rate of return on loans; r , the rate payable on funds borrowed to meet losses; M , a lump-sum penalty payable if funds must be borrowed; and ρ , the legal reserve ratio. The largest volume of cash outflow that can occur without causing a reserve deficit, the outflow that makes excess reserves equal to zero, is $v = (R - \rho D)/(1 - \rho)$. L is a stochastic variable with probability density $\phi(L)$. The bank's aim is to maximize its expected profit, P , where

$$(1) \quad P = iD - M \int_v^{\infty} \phi(L) dL - r \int_v^{\infty} L \phi(L) dL.$$

The mean of $\phi(L)$ is assumed to be a linear function of D , specifically, kD , k being < 1 in all of the examples in the paper. Orr and Mellon investigate the values of D that maximize (1) given various assumed values for the parameters.¹

¹ Orr and Mellon make other assumptions, e.g., that the variance of $\Phi(L)$ is independent of D , that are not at issue here.

A key characteristic of (1) that Orr and Mellon point out in a footnote to their Table 1, but do not emphasize, is that if i exceeds r , the bank maximizes profits by expanding D indefinitely. This is evident if one examines the profit function. As D increases, revenue, iD , increases by $i\Delta D$. But what happens to cost, the sum of the second and third terms in (1)? As $D \rightarrow \infty$, the integral $\int_0^\infty \phi(L) dL \rightarrow 1$ and so the term $M \int_0^\infty \phi(L) dL \rightarrow M$, a constant. If one considers the other term it is apparent that $\int_0^\infty L\phi(L) dL$ is a truncated expected value of L which $\rightarrow kD$ as $D \rightarrow \infty$, so $r \int_0^\infty L\phi(L) dL \rightarrow rkD$. With $i > r$ and $k < 1$, consequently, expected profit, P , increases continuously as $D \rightarrow \infty$. This property, it should be noted, is independent of the volume of excess reserves acquired by the bank at the beginning of the period. A bank with no or negative excess reserves would maximize expected profit by expanding D indefinitely.

Now the applicability of Orr and Mellon's model to banks in the United States, where the Federal Reserve frowns on borrowing reserves to make a profit, is unclear. Much more important, however, is the fact that banks in various other countries where no prohibition against borrowing to make a profit is in effect, have never been observed to expand credit indefinitely though the rate on loans has exceeded the bank rate on many occasions. The model implies behavior, in other words, contrary to that observed.

One can undoubtedly preserve some of Orr and Mellon's implications by making *ad hoc* adjustments to their model; for example, by making i a decreasing and r an increasing function of D . Their comparison of expansion under conditions of uncertainty with expansion as described by the traditional "deterministic" analysis cannot, however, be saved in this way.² A falling i and rising r does not rule out maximum profit values of D much larger than those predicted by the deterministic analysis and larger than those observed in actual practice.³

Orr and Mellon's discussion of what uncertainty implies about the creation of money by a many-bank banking system is also unsatisfactory.⁴ It may be readily granted that the standard textbook exposition of money creation by a many-bank system leaves much to be desired in its description of actual individual bank behavior. Its usefulness consists ultimately in its emphasis on the fact that individual banks will seldom if ever act like a monopoly bank, but that the banking system as a whole nonetheless does create money—a fact easily verified by observing the response of the money supply to a change in the reserves or monetary base of the system.

² Orr and Mellon identify the deterministic analysis with the assumption that $L = kD$ but always assume that $0 \leq k < 1$. The standard textbook illustrations assume that $k = 0$ for a monopoly bank (ignoring cash drain) and that $k = 1$ for a single bank in a system of banks.

³ Orr and Mellon fail to make clear exactly why the profit function (1) should not be reapplied in the next period to any excess reserves the bank has then, or in what respects what they describe as marginal credit expansion differs from total credit expansion. Their discussion of money creation by a many-bank banking system about to be noted indicates, however, that they do not envisage a sequential application of (1) to excess reserves resulting solely from the R of the initial period.

⁴ See [1, pp. 620-22].

Orr and Mellon's treatment of this matter is inferior to the familiar one. They conclude that credit expansion will be significantly less in a many-bank system than in a single-bank system. This conclusion stems from their assumption that the variance of the $\phi(L)$ applicable to a monopoly bank will be the sum of the variances of the $\phi_i(L_i)$ applicable to individual banks in a system of banks. The relevance of this assumption is not clear, and the conclusion conflicts with the observed behavior of the larger but still far from monopoly banks in our system whose aim in present-day circumstances is to hold virtually no excess reserves. Their exposition implicitly rules out, moreover, the relevance of the step-by-step, period-by-period, type of expansion described in the textbooks which is consistent with observed behavior.

In sum, Orr and Mellon's discussion is suggestive and moves in the right direction, but it fails to add significantly to our ability to explain actual behavior. Individual banks sometimes do hold excess reserves, but Orr and Mellon's model will not, in general, predict bank behavior correctly. In describing money creation by a many-bank banking system, moreover, we still must fall back on the type of step-by-step analysis familiar to all economists.

REFERENCES

1. D. ORR AND W. G. MELLON, "Stochastic Reserve Losses and Expansion of Bank Credit," *Am. Econ. Rev.*, Sept. 1961, 51, 614-23.

*The author is assistant professor of economics at the University of California, Los Angeles. He is indebted to Karl Brunner for a discussion of the points considered in this note.

Stochastic Reserve Losses and Expansion of Bank Credit: Reply

Miller's most devastating criticisms of our paper are two: (1) in our examples, we ignore the case in which i , the rate of interest on loans, exceeds r , "the rate payable on funds borrowed to meet losses [of reserves]" (as he puts it), or more properly "a penalty on each dollar of reserves the bank is short" (as we defined it on page 617 of the paper in question); and (2) our exposition of the credit expansion process is "inferior" and "unsatisfactory," since it "rules out . . . the relevance of the . . . period-by-period type of expansion described in the textbooks which is consistent with observed behavior."

1. Miller's alteration of the definition of r as noted above is critical: he has attempted to substitute a simple out-of-pocket cost for the penalty in our profit function. The literature on inventory decisions (to which we appealed for analogy in the first paragraph of our paper) is explicit regarding the appropriateness of the use of opportunity costs in the type of situation with which we deal. The profit function is, after all, an attempt to express the ramifications of all the various decision alternatives open to the firm (or bank) in utility (or dollar) terms. If this quantification is successful, intelligent policy measures can be obtained for the enterprise by simple mechanical manipulation of the profit function (for example, the manipulations in the

appendix of our paper). In the sixth example of Table 1 (p. 619) we tried to illustrate the absurdity of precisely the profit function coefficients suggested by Miller. Note b to that example points out that by setting r greater than i , one "takes into account only the money gained, and ignores such nonquantified factors as reputation for soundness." It should be noted that if the response of the profit function to changes in r and i is not linear as we have assumed [equation (4), p. 617], the stricture quoted in the preceding sentence would not necessarily be valid. Since our analysis is illustrative, rather than empirical, we used this linear response for computational viability. If it can be shown that the use of more satisfactory alternative forms of these responses jeopardizes the validity of our conclusions, we will defer to a valid criticism of our approach: meanwhile, Miller's rearrangement of the magnitude of r and i is not admissible for our model.

2. In elementary expositions of the credit expansion process, one encounters cascaded "generations" of banks; each generation receives as excess reserves the loans extended as a preceding generation expands credit in response to an excess reserve position. Miller associates a heuristic time period with each round in the credit expansion process, and he mistakenly identifies this interval with the time period referred to in our paper, the period at which the reserve positions of member banks are reviewed by the Federal Reserve System. (Nowhere do we use the word "period" to refer to any other time span: longer intervals are irrelevant because of the assumptions of footnote 4, p. 616; shorter intervals are ruled out by the assumptions of footnote 6, p. 616.) Miller is correct in suggesting that we take into account only one period of activity (which we attempt to justify in footnote 4); however, we do not thereby ignore all rounds of the credit expansion process which succeed the first, as he erroneously concludes. Our quantitative results on the systemwide expansion process (pp. 620-21) are in fact based on quite the opposite assumptions; we see the entire response as taking place within one of our periods.

Miller's misunderstanding of our paper is not confined to these two central points. We assume that the variance of the probability distribution of cash flows into and out of the banking system is invariant with the number of banks, and analyze the effect of the number of banks on the theoretically optimal volume of credit expansion. Miller finds this assumption indigestible on the ground that it conflicts with "... the observed behavior of the larger but still far from monopoly banks in our system whose aim is to hold virtually no excess reserves." That our assumption is not incompatible with Miller's observed empirical fact is evident from the conclusion that we draw: as the number of banks in the system decreases, the total precautionary reserve balances also decrease. For any bank the optimal level for these reserve balances is a function of the standard deviation of cash flows confronting the bank. A variance of 100 confronting a single bank leads to precautionary balances of some multiple of 10 (say $10k$); the same variance confronting 10 identical banks leads to total precautionary balances of $(10)^{3/2}k$; with 100 identical banks, precautionary balances are $100k$. We also mentioned the greater propensity of larger banks to make use of the federal funds mar-

ket, which may be taken as an alternative to (or reinforcement of) our explanation of Miller's observation.

In footnote 3, Miller raises two further points: we overlook the possibility of a sequential decision process, i.e., the individual bank might use a profit function similar to the one in our paper once each period; and we do not define the difference between marginal and total credit expansion.

In our analysis, we did not attempt to program the operations of a commercial bank: rather, we tried to draw conclusions regarding the effects of uncertainty upon the expansion of bank credit. In order to maintain direct comparability to standard results on excess reserves and the expansion of credit, we dealt with a highly artificial model. Any relevance that a sequential formulation might have for the task we undertook was deliberately dissipated by the assumptions of footnotes 4 and 6 of our paper, noted earlier in this discussion. It is quite true, but nonetheless irrelevant, that a carryover of excess reserves from one evaluation period to the next is indistinguishable from an injection of new free reserves at the beginning of the second of these evaluation periods.

The distinction between marginal credit expansion (net deposits created in response to an extra dollar of free reserves) and total credit expansion (the ratio of total deposits to total reserves) should be a familiar one.

BOOK REVIEWS

General Economics; Methodology

Analyse structurale et méthodologie économique. By ÉMILE LÉVY. Paris: Collection d'Économie Moderne, Éditions Génin, 1960. Pp. 291. NF30.

A four-page table of contents divides the volume under review into two *titres*: I, The Elaboration of a Structural Analysis; and II, The Integration of Structural Analysis into Economic Theory. These are further divided into *sous-titres*, chapters, sections, subsections, and subsubsections. There is no doubt about the author's intention to cover, at all costs, as much ground as possible. Past contributions, as remotely related as the sociology of knowledge and the Leontief system, are reviewed at a very quick pace. Within a volume of such a size, the author could not devote more than a couple of pages to the discussion of such important contributions as Marx's, Max Weber's, or Köhler's and Koffka's. Much too often the presentation of each contribution and the author's own comments on it takes the form of a table of contents: a series of brief paragraphs, each marked by a dash or a prominent dot.

In spite of the tremendous number of contributions reviewed by the author, there are regrettable omissions. Herbert Spencer is not mentioned at all, although a full section is devoted to biomorphism in social sciences. Alfred Marshall's biomorphism is mentioned only in passing. In the discussion of the relationship between business cycles and evolution, no reference is made to Marx or to Schumpeter. Instead, time and space are wasted on some minor, mainly recent, contributions. Even as a history of thought on the concept of structure the first part of the volume is unsatisfactory, for the reason that the author seldom, if ever, refers to the original sources. Köhler, Koffka, Max Scheler, Max Weber, and Veblen are presented through the eyes of some of their commentators. Strangely enough, Max Weber's theory of ideal types is summarized after Talcott Parsons, while the latter's, after Bourricaud.

The author's desire to *trop embrasser* is most conspicuous in the second part of the volume. It covers every chapter of economic theory; no name of an author of some repute is left out. This reviewer, at least, fails to see any connection between the concept of structure and such topics as Leontief's system, Sweezy's kinky demand curve, or even international trade.

It goes without saying that such a work fails to reveal the author's definite position on the nature and the role of the concept of structure. In the concluding chapter he admits that his purpose in writing the book was merely that of warning the reader about the obstacles connected with the concept of structure and making him thereby aware of these obstacles. This reviewer however, doubts that even this goal has been reached by the author. The well-informed reader knows—what the author appears to ignore in his work—that the concept of structure is a response to the impossibility of describing a qualitative world with aid of the structureless notion of number alone, and

that the opposition between the two is irreducible. The noninitiated cannot learn this object lesson from Mr. Lévy's survey of a vast number of subjects, many quite unrelated to his main topic.

NICHOLAS GEORGESCU-ROEGEN

Vanderbilt University

Allgemeine Wirtschaftspolitik. Vol. 1: *Grundlagen*. By DR. HERBERT GIERSCHE. Wiesbaden: Gabler, 1960. Pp. 356. DM 8.70.

This book, the first volume of a work intended to cover not only the principles but also the main branches of economics, is another in the series edited by Professor E. Gutenberg of Cologne. *Allgemeine Wirtschaftspolitik* is divided into six generous chapters. Chapter 1 lays the introductory groundwork outlining the subject-matter of economic policy and politics in general. Chapter 2 presents a short survey of the relevant problems of economic policy in the realm of social philosophy. Chapter 3 is devoted to welfare economics and serves as background for the consideration of the important economic policy systems, developed in Chapter 4.

Chapter 5 describes the forces in our present-day pluralistic society which attempt to influence the economic life and policy of the state. This section also contains a hypothesis as to the economic behavior of political parties and governments, and a short review of the goals, tasks, and possibilities of central banks, as well as those of the higher regional and communal authorities, insofar as they have an economic policy. Chapter 6 familiarizes us with the considerations which could lead to somewhat rational decisions and to a well-founded value judgment in economic policy.

On all these points Giersch's treatment shows in many respects interesting and independent thinking. The urgent problems of economic policy-making receive careful analysis; the descriptive and historical parts are rich in detail, informative and lucid, and well balanced. Good bibliographies follow each chapter. The despised tribe of nonmathematicians will rejoice at the complete absence of the usual arcanum of mathematical symbols and formulas.

Within the above-sketched framework, Giersch devotes perhaps somewhat more space and attributes more emphasis than expected to two problems. The first problem concerns the conflicts of goals and interests in the realms of social and economic policy. These conflicts represent the imperfectness of all human arrangements, and, unless they demand outright that we make clear decisions for or against individual ethical principles, they force us into compromises and solutions which are limited by some kind of a drawback. The second problem stems from the uncertainty, which lies like a veil over the future and over the economic reality of yesterday and today. Since we are not permitted to reach full certainty, every decision hides a risk, and at most we can only interpret pronouncements about socio-economic relationships as provisionally confirmed hypotheses; thus in reality and in science there is always room for positive criticism and constructive doubt.

Allgemeine Wirtschaftspolitik is a thoughtful and stimulating book, and a contribution on several levels. We are looking forward to its second volume.

GEZA GROSSCHMID

Duquesne University

Principles of Economics. By C. E. FERGUSON AND JUANITA M. KREPS. New York: Holt, Rinehart and Winston, 1962. Pp. xii, 852. \$7.95.

The authors, conceding that we already have "excellent texts," offer a fuller treatment of price stability and growth to supplement the now customary emphasis on full employment. The gap is being filled by others as well (thus Samuelson's index had 10 page references to inflation and none to growth in 1951, but 83 to both subjects in 1961, the work under review having 81), but this addition can be welcomed on its own merits. The book is well written; its organization has new features; its forte is rigorous proof of principles.

Seven algebraic and geometrical appendixes deal with such recondite matters as the classical solutions of the duopoly problem, the derivation of the production-possibility curve, and the optimum conditions of factor and product substitution. The reviewer would not merely leave these "to the discretion of the superior student": he would move most of them outright to a text on intermediate theory—i.e., to its appendixes. Until our first course does more for the mass of undergraduates (future voters), it is doubtful efficiency to use 6 or 8 per cent of the space for one or two brilliant students, sometimes none, per class.

If the 40 text chapters and the appendix on accounting are completed in 80 assignments—21 chapters are designated for one-semester courses—an average student would use probably 45 to 60 minutes per preparation. This would call for a book of readings to accompany the text. The popularity of such readings and the standard 700-900 page length of texts tell the reviewer that his preference for a book 500 pages longer puts him in a minority so small that no producer (since the death of Taussig and retirement of Fairchild, Furniss, and Buck) will cater to it. Outside readings cannot supplement the text as well as an author himself could do with additional detail; and readings rarely command the student's or teacher's full attention.

The first half of the book under review is divided as follows: (1) goals, economic laws, resources, and the operation of a market economy; (2) supply, demand, and national income; (3) most of employment theory; (4) money and public finance; and (5) a "synthesis of the classical and Keynes system" (using Hicks) plus comments on economic policy. The chiefly microeconomic, or second-semester, sections are (6) the firm, competition, and pricing; (7) control of business, labor, and agriculture; (8) income distribution; (9) "A Review of Theories and Controls"—chiefly cost-price inflation, welfare economics, and workable competition; (10) international trade—emphasizing the recent United States payment deficits; and (11) comparative economic systems and development. Parts 2, 3, 4 and 6 comprise more than half the volume. Titles of sections and chapters are introduced intriguingly by such words as "Objectives," "Policy," and "Controls."

The space given to each topic is always a matter of opinion. The reviewer regrets that wage, rent, interest, and profit theory are squeezed into one chapter (plus the treatment of liquidity preference under employment theory), granting that there are chapters on marginal productivity and income inequality also. Analysis of occupational pay differences is down to eight lines. One may question whether time of elementary students should be allocated to

welfare theorems, input-output data ("the most important table in the book," however, in the authors' view), and brilliant but not yet established hypotheses of Ackley, Baumol, and others—especially the authors of the 1959 Joint Economic Committee *Staff Report on Employment, Growth and Price Levels*.

The orientation of the book toward theory, anticipating a good deal of the standard intermediate course, will call for help from the instructor in such passages as those on the Domar and Harrod growth models. In teaching this book, as with others, wider than usual divergences of the real world from theory should be mentioned in class: these are sometimes but not always indicated by the authors. Teachers may also note when practical proposals, reported if not always endorsed, do not necessarily follow from the proven theories. The reviewer has sent the authors his own suggestions of detail, along these and other lines, for the second edition he anticipates in three or four years.

This is a promising text for teachers desiring to emphasize principles. Perhaps the ordinary undergraduate with good instruction will prove that he can "take it," or perhaps the book will match the proved appeal of Boulding's *Economic Analysis* for superior students. It was worth while to read, and should be also to teach. The reviewer regrets that he could not have used it in class before attempting an appraisal.

SIMON N. WHITNEY

Rutgers—The State University

The American Economy. By B. G. FISHMAN AND L. FISHMAN, in collaboration with others. Princeton: Van Nostrand, 1962. Pp. xxii, 822. \$7.95.

This recent elementary textbook should perhaps bear the subtitle: history, institutions and public policies. It is a collaborative work including chapters by ten other writers in addition to the authors listed above.

The purpose of the book, as indicated in the preface, is to discuss those aspects of economics which are likely to be useful "in the every day life of a college trained citizen of the United States. . . . Theory has not been ignored, for theory has much to contribute in understanding our economy. But those refinements of theory useful primarily to a small group of professional economists have been avoided." Rarely do texts fulfill their "prefatory intentions," but this one does. One would wish to question, however, the choice of theory which the authors consider to be the arcana of the profession. The text is largely a nonanalytical reference work almost encyclopedic in scope. The student is not likely to be confused by sticky diagrams dealing with the theory of the firm—there are none. There are six analytic diagrams in the entire text limited to demand and supply analysis. Price determination under monopoly is neatly handled with a nine-line quotation from the last edition of Kiekhofer's text. The student is further assured that economists for the most part would accept this statement as a concise and correct statement of monopoly price theory (p. 85). Q.E.D.

One wonders how meaningful the discussion of the incidence of taxation can be to the student when some 300 pages after his meager introduction to

marginal concepts he is told that: "If a business was maximizing profits before any tax, an income tax would not affect marginal cost or marginal revenue and thus would not affect the price-cost-output equilibrium" (p. 395). Indeed, economic analysis will remain a mystery if conclusions based on a "price-cost-output equilibrium" have not explicitly appeared previously in the text.

The materials on macroeconomics also suffer as a consequence of avoiding "analytical refinements." It is difficult to see why the authors find it desirable to distinguish among the consumption function, the "average consumption function" and the "marginal consumption function" in their abbreviated exploration of the determinants of aggregate income (p. 210), using numerical examples exclusively. College students, presumably, have been exposed to geometry in high school.

The book is organized along conventional lines: the first Part deals with the structure of the U.S. economy; Part II is concerned with prices, income and output; Part III deals with changes in the level of economic activity; Part IV describes the monetary-fiscal functions of government as well as problems related to international trade; Part V covers public policy related to economic stability and security; Part VI is concerned with public policy toward private associations and sectors of the economy; Part VII compares capitalist and socialist economics.

The book is well written and in some respects much too comprehensive for an introductory text. What the authors exclude in analytical economics they more than compensate for by extensive historical and descriptive coverage. One would perhaps wish that the reader might be spared the long leap between chapters describing specific sectors of the economy and later chapters discussing problems faced by these sectors and related public policy. Chapter 3, for example, describes the farm sector of the economy but the farm problem and public policy toward agriculture are not dealt with until the reader arrives at Chapters 41 and 42.

Junior college and perhaps advanced high school students may find this text a good introduction to the subject matter of economics.

Colgate University

**Price and Allocation Theory; Income and Employment Theory;
Related Empirical Studies; History of Economic Thought**

Principles of Economics. By ALFRED MARSHALL. Ninth (Variorum) Edition with annotations by C. W. Guillebaud. London: Macmillan and Co. Ltd., for the Royal Economic Society, 1961. Vol. 1 (Text), Pp. xxxiv, 858; Vol. 2 (Notes), Pp. ix, 886. £6.00.

The first volume of this variorum edition of Marshall's *Principles* consists of the text of the eighth edition, reset in larger type yet retaining the original pagination which is substantially that which has existed since the fifth edition, with a number of misprints corrected, and with signs inserted referring to editorial notes in Volume 2.

In Volume 2 the aim of the editor has been: (1) "in the case of every paragraph or sentence in the eighth edition to indicate from which edition that paragraph or sentence originated"; (2) "to indicate any changes of substance which took place in any paragraph or sentence before it reached the final form in which it was carried in this eighth edition"; (3) "to reprint material which has appeared in any edition of the *Principles*, but which is not contained in the eighth edition"; (4) "to provide a new and more comprehensive index to the *Principles*"; (5) "to reprint articles written by Marshall to which he refers in the course of the eighth edition of the *Principles* and which have not been reprinted in the *Memorials of Alfred Marshall*"; also to reprint some other relevant writings of Marshall, including the "Plea for the Creation of a Curriculum in Economics and Associated Branches of Political Science" (circulated to members of the Senate of the University of Cambridge in 1902); and, finally, to print some previously unpublished letters (e.g., after the notes on Appendix F, Barter, are printed two letters from Marshall, and one from his friend Arthur Berry, to F. Y. Edgeworth with reference to his article in the *Giornale degli Economisti* of March 1891).

The complete separation of the text and the notes, and the unobtrusive character of the reference symbols in Volume 1 make for easy reading of that volume, rendering it very useful for those who want to read the *Principles* in its final form and who are not interested in the variant readings. Nevertheless, there is some disadvantage in having to turn to a second volume for the dating of every paragraph. I write sympathetically and doubtfully about this for I am now participating in the production of a variorum edition of John Stuart Mill's *Principles* (to be published, I hope, in 1963, by the University of Toronto Press). We face the same problem of how to produce a new edition which can be read for itself, and yet which provides a suitable apparatus for the scholar who wants to study the variant readings.

The instructions to reviewers sent by the editor of this *Review* include the following item: "It should be self-evident that a book should be accepted for review only if the reviewer is prepared to read the entire work carefully." It will be clear to anyone who has used this edition, and even more clear to anyone who has worked on the preparation of a variorum edition of any comparable work, that this instruction cannot be taken literally in the present case. All I could do is to sample. On the basis of such sampling I find ample justification for the view expressed by Guillebaud in his article on "The Variorum Edition" of Alfred Marshall's *Principles of Economics* in the *Economic Journal* (December 1961): "The impression I myself have gathered from working through and collating the different editions of the *Principles* is that changes which took place in them throw an instructive light on the development not so much of Marshall's thinking, as of the way in which he expressed his thought." In the "Editorial Introduction" to Volume 2, Guillebaud says: "Edgeworth, who reviewed the first edition in the *Academy* and the second and third in the *Economic Journal*, found nothing that he would single out as representing a new idea or change of doctrine. In general it may be said that Marshall's major economic theories and doctrines were already crystal-

lized in their final form, in content though not in expression, when he brought out his first edition." Because there was so little fundamental change and because the amount of change is nevertheless so great, it would have been very helpful if the editor had given us some clear indication of the significant changes. And it would have been particularly helpful to have these changes related to his other writings and to the writings of others.

In the sample that I have examined I found no omissions comparable to those referred to by G. J. Stigler in his excellent review article, "Marshall's *Principles* after Guillebaud," in the *Journal of Political Economy*, June 1962. One's confidence in the apparatus of variorum annotation is shaken by the examples there cited. But Stigler raises a more difficult question when he asks whether a variorum edition is useful, and whether an annotated edition would not have been more valuable. As I struggle with the variant readings of Mill's *Principles*, I am afflicted with similar doubts, and my examination of this edition of Marshall does not allay them. The more complete the apparatus of variant readings, the more danger there is that the real process of development of ideas may be hidden in the mass of detail. Having compared the full variorum annotation of Mill's *Principles* with the references to earlier editions given by W. J. Ashley in his edition of the *Principles*, I find myself wondering whether our new edition will be as useful to working economists as his. But, to return to Marshall, I think that this variorum edition is useful and that economists owe a debt of gratitude to Guillebaud for his years of work on it. I find it hard to think of an annotated edition that would not be so massive an encyclopaedia as to be quite unmanageable. There is so much to be thankful for in this edition that I do not think we should complain about the other things that might have been done.

The University of Toronto

V. W. BLADEN

Lectures on the Mathematical Method in Analytical Economics. Mathematics and Its Applications. Volume 1. By JACOB T. SCHWARTZ. New York: Gordon and Breach, 1961. Pp. xi, 282. \$14.50.

Contrary to the expectation induced by its title, the present volume is not a methodological inquiry into the use of mathematics in economic science. Rather, Schwartz presents some mathematical models of the Leontief variety, most of which are intended to elucidate the causes of the business cycle. Since the book is the outgrowth of the author's lectures at New York University, it is largely expository; yet his own contributions are not insignificant. A moderate level of mathematical competence is required of the reader (especially important is a familiarity with results on nonnegative matrices and with elementary topology), but Schwartz does a lucid job with the verbal interpretation of his mathematics.

The book consists of three parts: a discussion of the closed Leontief model (pp. 1-56); a theory of inventory cycles (pp. 57-178); and a discussion of a modified Walrasian system in the context of the existence of competitive equilibrium (pp. 179-278). These diverse topics are rather loosely and inef-

fectively linked by an input-output framework employed in each of them, on the one hand, and by the author's apparent view of himself as a defender of Keynesian doctrine, on the other.

In the first part Schwartz formulates the static Leontief system in terms of the price dual, and hence he is led to include a matrix of capital coefficients and a profit rate along with the coefficients of current inputs in the system of price equations. Each type of labor is viewed as a separate commodity with its own price and technology. These equations are solved for relative prices and the economy-wide rate of profit. After a neat review of some of the results on connected, nonnegative matrices, the author concludes with the familiar result: a necessary and sufficient condition for positive prices and rate of profit is that the dominant root of the current technology matrix is less than one (i.e., that the economy is viable in terms of current inputs). He also notes that the rate of proportional accumulation of stocks cannot exceed the solution value of the profit rate.

Far more interesting is the author's construction of a multisector model of the inventory cycle. Although most of his discussion deals with an aggregative version of the model (made possible by an assumption that initial output and inventory levels in the Leontief-like economy are proportional to the positive characteristic vector corresponding to the dominant root of the input matrix), Schwartz later generalizes some of his results to the case of an "unbalanced," multisector economy. The basic structure of the model is essentially an interindustry version of the original Metzler inventory theory [4]; whereas its dynamic motion has much in common with a trendless version of Hicks' *Trade Cycle* [2]. Schwartz gives the Metzler formulation nonlinear features by constraining inventories and output to be nonnegative and output to be feasible (as technologically determined by the carry-over of inventories from the previous period). These two constraints provide a floor and ceiling to output in each period.

By assuming that the economy-wide input-to-output and desired inventory-to-sales ratios are suitably large, Schwartz is able to conclude that the unconstrained analogue of his model has positive and unstable roots—i.e., the system explodes in a noncyclic fashion. Once actual output and desired output diverge due to an encounter with the ceiling (existing inventories are insufficient for sustaining the desired level of output), there may occur an indefinite "crawl along the ceiling" in the manner of the Matthews model [3], or a downturn as in the Hicks cycle and Nelson growth model [6]. The latter will prevail when the accumulation of inventories along the ceiling is sufficiently rapid to overtake the desired stock of inventories, and this will happen when the desired inventory-to-sales ratio is assigned a low value (but not so low that the noncyclic, explosive character of the unconstrained path is destroyed). The lower turning point is the result of persistent decumulation of stocks in the face of autonomous purchases which exceed a zero level of output—until desired inventories exceed the depleted stocks, at which point output shoots upward. Nowhere in the cycle does the stock of human beings limit output; full employment of labor, presumably, is never achieved. Fur-

thermore, nothing is said about the cyclical behavior of the rate of profit, to which the author devoted so much attention early in the book.

Although the instability of the model prevents its attainment, the equilibrium value of output in Schwartz's system is the familiar equilibrium solution of the matrix multiplier (see Chipman [1]). But the author does show that the Keynes Point (as he calls this solution) is the average value of output as the system proceeds along its limit cycle. In addition, he has a nice demonstration of the way in which the instability of the unconstrained system can be converted to stability by means of distributed lags in the formation of expectations as to future sales, a result closely resembling some recent work by Metzler [5].

Whereas output levels over time are the author's concern in the second part of the book, the last section presents a static, general equilibrium theory of prices. The existence—and at times, the optimality—of an equilibrium, rather than its stability, become the central issues. As a first approximation, fixed input coefficients of produced goods are retained, in which case the entire problem is resolved into a determination of the wage rate (and hence profit rate) in the labor market. The proof of existence is handled in much the same way for the more general case of variable input proportions. But with the aid of several empirical assumptions of the most casual sort (e.g., labor and capital are not very good substitutes anyhow), Schwartz uses the results of the fixed-coefficient model to make a rather ineffective argument for a general rise in wages as a cure for a contrived underemployment situation in which the labor supply function has a convenient (for the author) discontinuity. Although the formal analysis is up to the author's high standards, the incessant polemical tone of this section of the book is a significant deduction.

More stringent editing would have made a substantial improvement in the book—to use Henry Hazlitt as a whipping post in the rarified atmosphere of fixed-point theorems, nonnegative connected matrices, etc. is simply out of place. In addition, lengthy sections devoted to presentation (and a minimum of manipulation) of empirical data add nothing to the theoretical results. Admittedly, Schwartz claims only that these data put matters in the proper perspective, but they fail to achieve even that modest objective.

Finally, although Schwartz's central propositions in no way depend upon them, one can raise objections to certain of his arguments. For example, he assumes in his expository discussion of the Leontief system that capital items are not required in the "production" of labor, unlike the technological requirements of other commodities. But certainly houses and other consumer durables rather naturally fall into the category of labor-producing capital goods. (Of course "dummy" industries can be created to sell the services of these capital items to the labor sector, thereby effecting a formal elimination of capital from the production process in that sector; but this is not done for other commodities, and there seems to be no compelling reason for so doing with the labor sector.) By eliminating capital from the production of labor, Schwartz's assumption has the effect of forcing the return of capital in

labor to be zero—a rather disturbing result, one would suppose, for the sizable number of economists currently investigating the return to investment in human beings.

In much the same spirit, Schwartz assumes that human capital is not required in the production of any commodity, human or nonhuman. Although this is also a matter of choice between stock and flow approaches to production, it is convenient in certain instances to view a human being as a capital item—e.g., in those circumstances where “retainers” are paid.

From his later exposition one infers that Schwartz’s reason for these assumptions is to preserve the simple form of the matrix of capital coefficients in a derived model in which a prior solution for labor inputs eliminates their explicit appearance. But nowhere in his later analysis of the labor-eliminated model is the simplified capital matrix critical for his results. In brief, the assumptions unnecessarily restrict the situations to which his model might apply.

But these are minor imperfections in an otherwise worth-while book, and it deserves the attention of those economists with some mathematical training. Although it is unlikely to become a significant landmark of mathematical economics, the present volume indicates that this series of monographs of which it is the first will be of use to economists.

Preistheorie. By WILHELM KRELLE. Zürich: Polygraphischer Verlag; Tübingen: J. C. B. Mohr (Paul Siebeck), 1961. Pp. xxiv, 732. DM 63; paper, DM 56.

In the first part of this book, the author summarizes contemporary price and market theory, including the derivation of demand and production functions. This as it were sets the stage—the economic background for the individual firm’s maximizing activities. The rest of the book is concerned with the para-

functions which describe rational firm behavior. In the final chapter shows—or attempts to show—how the maximizing equations lied in practice, “as soon as the necessary underlying data can . . .” (p. 629).

of the book is then the individual firm and its decisions; and theory as such or problems of general equilibrium. There is much of more general theoretical interest, including particularly concept of a limit or threshold of sensitivity (to the effects of price and other variables), his theory of negotiations, and his dealing with risk and uncertainty. Throughout, the author first subject verbally together with diagrams in the text, and replete with appendices, attached to the individual sections of the text, including more abstruse mathematical analysis, and criticism of various approaches and solutions.

the firm as such, Krelle follows the order: monopoly, duopoly, then—although “a text book of price theory is no cook book of the situation” (pp. 195, 245)—bilateral monopoly and “more complex relationships.” For each of the major market forms, he discusses possible goals: profit maximization; sales maximization with perfect competition and profit maximization with a minimum of sales; and distribution between classical and “Leontief” production functions. He discusses maximizing functions with certainty, including in the cases of lack of knowledge of rivals’ reactions, the author brings in uncertainty considerations. In connection with uncertainty, he distinguishes situations of known and unknown probabilities, and also distinguishes—once for all—decisions under uncertainty.

Next is the author’s analysis of duopoly—and by implication of bilateral monopoly—with “incomplete mobility” of demand, that is, non-homogeneous products. The essence of the situation is the (correct) anticipation of the duopolists that the rivals will react in asymmetric patterns to upward and downward price revisions. This is of course the “kinked” oligopoly demand curve; but Krelle, by bringing in the fact of heterogeneous products, demonstrates the existence in most circumstances of an *area* of possible stable equilibria (more or less rigid prices) so long as competition is “peaceful.” The particular solutions (arrays of prices of the rivals) depend on historical and also psychological (subjective) factors. In this section, the author points out that other theories of duopoly-oligopoly—from Cournot to Stackelberg—assume “more or less significant errors of one or both rivals with respect to the reciprocal reaction . . .” (p. 350), and also in some instances stubborn refusal to revise patterns of conduct in the face of continued disappointment when rivals do not react as anticipated.

Krelle’s own solutions are based on “full insight” into market conditions, including in the first approach, correct evaluation of reactions (strategies) of rivals or, in the cases of bilateral monopoly, market opposites. Thus the author, in his approaches, rules out bluff, deception, error, and uncertainty. With respect to bilateral monopoly, the author demonstrates that—with full

knowledge on the part of the two monopolists—there is no problem of quantity, but only of price. That is, what is involved is the division of the monopolistic spoils (contrast the theory of countervailing powers). Incidentally, in an aside to his "Practical Rules for Negotiations," Krelle brands bilateral monopoly as "so to speak . . . an immoral institution" because "it places an overly high premium on deception of the opposite side" (p. 452).

The author in all these situations brings in uncertainty with respect to rivals' strategies and also "nonpeaceful" strategies, after reaching solutions based on correct knowledge of rivals' reaction parameters and "peaceful" intentions. His use of graphic illustration is ingenious, in particular, iso-profit contours with the two variables being the prices of the two firms. Of interest also is his use of the concept of "economic horizons" (of individual firms) in connection with economic warfare, and his theory of (rational) negotiation.

The book—as is evident from the foregoing—is addressed particularly to the practicing economist who, in employment of the firm, will attempt—with the aid of electronic and even "superelectronic" equipment—to apply the theories, that is the maximizing equations, to solve the complicated problems of optimal firm "programming." Your reviewer, because of inadequate mathematical background, is unable to evaluate the specific mathematical procedures and examples, whereby the solutions of the earlier chapters are transformed into hypothetical production and pricing programs. Two aspects of the procedures however seem relevant: first, the "very wearisome" (p. 660) burdens of solution even with electronic equipment; and second, the difficulty of obtaining or estimating the parameters and functional relationships with which the equations are to be given substance. "Such exact data" are in fact "naturally not to be anticipated," either in the oligopolistic example given by the author (p. 714n.) or in many other instances.

The fact, however, of the author's *possibly* exaggerated hopes for practical application of complicated formulae to business problems, and his primary interest in business-firm behavior do not lessen the book's interest for the theoretical, and also for the governmental, economist. The former can profit in particular by the cogent criticisms of contemporary price and firm theory, as well as the several original contributions to theory and methodology. Altogether this book marks a milestone in the economic analysis of decision-making, and in the implications for entrepreneurial behavior of the theories of markets, of risk and uncertainty, and of negotiations.

Economic History; Economic Development; National Economies

American and British Technology in the Nineteenth Century: The Search for Labour-Saving Inventions. By H. J. HABAKKUK. New York: Cambridge University Press, 1962. Pp. 222. \$6.00.

In this book one of England's leading economic historians, H. J. Habakkuk, Fellow of All Souls and Chichele Professor of Economic History in Ox-

ford, uses economic theory with considerable sophistication to speculate on why the level of labor productivity and the rates of invention and technical progress in manufacturing were greater in the United States than in Britain from Waterloo to the First World War. He suggests that "economic," not "sociological," factors lay at the root. Sociological differences, insofar as they existed, arose from economic differences.

The author argues that America's high wage rates, made necessary by high farm earnings, created an incentive to develop and use capital-intensive techniques. The dispersion of population, moreover, made the industrial labor supply inelastic in expansion. Hence, "shortages" of labor when investment was high constituted an added stimulus. The author argues further that before the onset of heavy immigration in the 1840's and 1850's, unskilled labor was relatively scarcer in the United States than in Britain. In consequence complex machines made with skilled labor had a comparative advantage in the United States; and this, particularly when skilled labor was needed to operate such machines, fostered mechanization here. After immigration augmented the supply of unskilled labor, America benefited from skilled-labor-saving technology originating largely abroad, while high wages continued to provide a general inducement to mechanize. The saving of skilled labor in the post-Civil War period was further stimulated by the growing belligerence of unionized skilled workers. By contrast, British industry could draw upon a large reserve army of underemployed ruralists at low wages until about 1870, and therefore lacked the same incentive to develop or use capital-intensive methods. (Eighteenth century Britain, however, before the big surge of population growth and the late enclosures, confronted a shortage of industrial labor and responded with a spate of labor-saving inventions as did America in the following century.)

While high relative wages ordinarily depress total investment, the high rate of growth of the U.S. economy as a whole, reflecting the building up of the country, Habakkuk contends, assured a high rate of investment here. In addition to the presumably overriding stimulus to investment provided by growth, the author suggests that the depressing effects of high wages on investment were partly offset by the need which such wages imposed for greater efficiency, by the superior qualifications and longer working hours of U.S. workers, their greater receptivity to technical change (arising from labor scarcity), and a higher entrepreneurial propensity to save induced by the use of capital-intensive techniques. Still another factor favorable to investment which Habakkuk stresses was monopsonistic and monopolistic profits in manufacturing made possible by the local and regional character of many U.S. labor and product markets.

In Britain, on the other hand, after 1870 wasteful entrepreneurial practices and labor hostility to labor-saving techniques—attitudes originally engendered by low-cost, abundant labor—continued through force of habit after the economic conditions which gave rise to them had abated. Toward the end of the century Britain's industrial growth was, moreover, retarded by the declining magnitude of the rural-urban shift, and by the rise of industry abroad, particularly in Germany and the United States.

While one might expect that low labor costs would induce labor-saving invention and innovation, and to some extent did so, Habakkuk argues, the possibilities for such improvement were few in the case of labor-saving. Natural resources are usually more heterogeneous than labor, he suggests, so that techniques which save them generally have only a narrow application. Moreover, since natural resources constitute a smaller part of total costs than labor, profits from natural-resource-saving inventions will not be great. Further, the possibilities for improvement are greater at the labor-intensive end than at the capital-intensive end of the spectrum of techniques, because, Habakkuk contends, mankind has had longer experience with the former than with the latter. In the light of all these considerations, he argues that if Britain's nineteenth century entrepreneurs were inferior to those of the United States and Germany, it was because the British industry offered inferior opportunities to men of high talent; in Britain, economic—or at least nonmanufacturing—employments secured a larger share of the nation's talent in England than in the United States or Germany.

Taken on its own terms as a speculative foray into a complex subject, Habakkuk's book is a valuable and stimulating contribution. It illustrates how the study of economic history can be enriched by the intelligent application of economic theory; it suggests the possible existence of interdependencies which are disregarded in theoretical analyses; and it raises significant questions for further research. Some of these may be indicated briefly here. First, as Habakkuk fails to recognize the possibility that in many U.S. industries, labor costs per unit of output may have been lower than in Britain for the same technique. Thus Habakkuk frequently notes that, compared with British workers, U.S. workers were better educated, stronger, healthier, more productive, and worked longer hours, had a higher average level of skill, and not only did not shirk but often actively sought improved techniques; it may be, as Leontief has argued in another context, that measured in efficiency-units U.S. labor was cheap, not dear. If this is the case, and the condition was general, the basis of Habakkuk's argument which rests on high wages falls to the ground. What is relevant is labor costs per unit of output, not labor costs per worker. Likewise, the author's contention that the possibilities for improvement are greater at the capital-intensive end of the spectrum, if true, become of less practical relevance. The distinction between "sociological" and "economic" determinants also needs clarifying, a need highlighted by Habakkuk's (unavoidable) oversimplification of regarding as a sociological variable genetic differences in inventive ability. Similarly, the "perverse elasticity of credit" in the Federal Reserve Bank era suggests that in booms, capital may have been at least as scarce as labor. (Incidentally, some readers are bound to be puzzled by his frequent use of "shortage," a term which he does not define.)

Once the various possible factors have been identified, assigning relative weights to them is the next problem. For example, while it is true that economic conditions fostered a more rapid rate of inventive and technical progress in the United States than in Britain, most of this difference could still be the result of "sociological" factors. It is not enough to show that observed economic differences between the two countries

produce differences in invention and productivity *in the same direction* as those observed. It is also important to know whether they produced differences of the same magnitude. This question cries for an answer when U.S. economic history is compared with that of other regions settled at more or less the same time but by men who brought with them a radically different ethos. To put the matter somewhat differently, were those distinctive, progress-oriented American traits which perceptive observers so frequently noted in the eighteenth and nineteenth centuries merely a product of factor proportions, or were they mainly a consequence of the selective character of American immigration?

The book is slightly marred by occasional minor theoretical errors, as, for example, on page 14 where the author suggests that high farm earnings forced U.S. manufacturers to pay the marginal worker more than the value of his marginal product; or in a note on page 38 where he assumes that his analysis is inconsistent with the assumption that returns to U.S. agriculture were usually below those to industry. (Imperfections aside, average returns on capital, sunk costs included, could have been lower in the former than in the latter while returns on new investment were the same.) The footnotes and textual evidence are of considerable independent interest. The index is inadequate.

JACOB SCHMOOKLER

University of Minnesota

The Industrial Revolution in Europe, 1815-1914. By W. O. HENDERSON.
Chicago: Quadrangle Books, 1961. Pp. ix, 288; maps. \$6.00.

The term "industrial revolution," having undergone successive inflations and deflations, has in recent years taken on a generally accepted and fairly specific meaning when used by economic historians. It has come to refer to a period of marked acceleration in the rate of economic growth, accompanied by industrialization and pervasive changes in the character and tempo of economic life, which ushers in an era wherein the rate of growth is sustained at levels appreciably higher than those hitherto enjoyed. Henderson's study of France, Germany, and Russia is not clearly reconciled to adopting this concept, with its emphasis upon discontinuity and pervasive change, in preference to a more liberal use of the term which would apply it both to the mechanization of manufacturing activities and to a hundred-year epoch in economic experience.

A full treatment of the economic development of three major European countries during the period 1815-1914 could not reasonably be attempted in a book of these modest dimensions. On the other hand, a group of intensive studies, confined to analysis of the periods of acceleration, or a comparative examination of selected aspects of the industrial development of the three countries, structured around one or more major hypotheses, suggest themselves as feasible and worthwhile ventures. Henderson's opening chapter seems to hint that something of this order is in store for the reader. But it is just a hint. In place of a set of hypotheses which can fruitfully be subjected to a

fresh examination we are presented with an incomplete account of Rostow's "stages" and a surprisingly inadequate summary of W. Hoffman's research on patterns of structural change in industrial economies—surprising, since Henderson was co-translator of Hoffman's work. Moreover, for better or worse, nothing is heard of Rostow's or Hoffman's theses in the pages that follow.

Instead, the body of the book is divided in three parts: half the volume being devoted to France, with Germany and Russia sharing the balance in the ratio of 3 to 2. The parts are virtually unrelated and contain straightforward accounts of developments in the fields of industry and transportation between 1815 and 1914, through which bits of condensed political, working-class, and colonial history are interspersed—some of them being only tenuously connected to the announced central theme of industrialization.

For the most part, Henderson is content to describe, rather than search for any underlying logic in a given procession of events. Describe he does. The reader is offered a narrative laden with details whose significance for industrialization generally remains unexamined, and on occasion would not bear such examination. Of what import is it that the quay built at Bordeaux in 1856 was 700 meters in length, or that Yermak led 800 men against the khanate of Sibir in 1574, or that the firm of Woermann "traded successfully" in the Cameroons and Gaboon? Yet, midst all this raw empiricism, nowhere can the reader find any systematic, convenient presentation of available quantitative information. The pages are sown with industrial output, labor force, and other statistics (real national income is mentioned once in a footnote) by the broadcast method. Anyone wanting a rate of growth will have to search out the components, worry about comparability, and compute it himself. Those seeking the sources of the data given will be disappointed, for the work is entirely without annotation. The latter is particularly distressing when it is left unclear whether the numerous unidentified quotations are in fact direct quotes or translations. A selective bibliography is supplied, but since it is confined to English-language publications it must perforce omit all primary sources.

As an approach to the study of industrialization on the Continent, the book suffers from even more serious defects. Henderson's treatment seems to imply that preindustrial conditions in different regions of Europe had little influence in shaping the course of subsequent developments; and it is precisely his failure to fully examine the preindustrial economies of the countries involved which effectively removes any means of evaluating the relative significance of members of the traditional array of factors listed as contributing to industrialization, or, for that matter, of understanding why the process of industrialization differed among countries in timing, speed, and resulting economic and institutional structure. Indeed, by stressing the role of British entrepreneurs on the Continent—a field in which his scholarly contributions are well known—Henderson at times seems to further suggest the view that the "industrial revolution" started in England and was literally spread abroad. But just as no attempt is made to account for the greater role played in Russia than in France by government, or for the difference between the functions assumed by banking institutions in the course of German and Rus-

sian industrialization, we are left to wonder why, for example, Englishmen were able to do so much for early industry in Upper Silesia and so little in France.

It is symptomatic of the general glossing of the problems confronting pre-industrial Europe that Henderson's only apparent device for limiting the scope of the work consists in neglecting the agricultural sector. Arthur Young's comments on the progressive aspects of some farms are taken to suffice as a portrayal of the French agrarian situation in the latter part of the 18th century—which may be why the dominant position of small peasant proprietors in 19th century French agriculture is ascribed, *en passant*, to the revolutionary reforms of 1789-93. The question of agrarian reform in Prussia is barely alluded to, and all told, roughly one page is devoted to the emancipation of the serfs in Russia and one paragraph to Stolypin's reforms. It is therefore perhaps not surprising that the difficulties encountered in the recruitment of industrial labor in Russia after 1861 are not assigned in any part to the restraints placed by the *mir* on the permanent transfer of peasant out of agriculture, but rather are put down to the fact that peasants found industrial employment "uncongenial" and factory discipline "irksome."

The shifts in interest, changes in concept, and the progress of research during the 40 years since the appearance of J. H. Clapham's *Economic Development of France and Germany* all cry out for a synthetic re-examination of Continental industrialization which can take a place alongside that classic work. Unfortunately, it is a plea that goes unanswered in this volume.

P. A. DAVID

Stanford University

The Rate and Direction of Inventive Activity: Economic and Social Factors.

A Conference of the Universities-National Bureau Committee for Economic Research and the Committee on Economic Growth of the Social Science Research Council. NBER Special Conference Series No. 13. Princeton: Princeton University Press for National Bureau of Economic Research, 1962. Pp. xi, 635. \$12.50.

These 23 papers, originally prepared for a conference at the University of Minnesota held in May 1960, form a collective attempt to domesticate that coarse, exogenous variable, technological change. Armed with National Science Foundation and Patent Office statistics, case studies, patriarchal and up-to-the-minute economic concepts, and aided by psychologists, sociologists, and historians of science, the participants report much progress and hint of more to come.

Yet, according to most of the authors and practically all discussants, many quandaries remain. Prominent among these is the problem of defining terms and staking out a manageable field of inquiry. After some soul-searching, Kuznets accepts the conventional triple categories of scientific research, invention, and improvement, which correspond roughly to the current usage of basic research, applied research, and development. To him the middle category, defined as the combining of "existing knowledge in devices potentially useful in economic production and resulting from a mental performance above

the average" (p. 24), is sufficiently distinct to warrant nineteen pages exploring its measurability. But only a half dozen of the other papers are that narrowly focused. Most cover the entire spectrum of activities preceding the first commercial or military use of a new commodity or process. And the conference was the better for it.

Those authors who agree with Kuznets in finding inventive activity, narrowly defined, a useful concept, do so partly because the patent system, like a customs house, generates statistics at a more or less arbitrary frontier. In this class are Thompson's paper showing a correlation of patents granted with urbanization and industrial structure and MacKinnon's demonstration that mediocre independent inventors have different psychological profiles from patent-holding mediocre corporate research workers.

The patent system itself is the subject of Markham's review of the way in which a more vigorous antitrust policy since the 1930's has weakened both protection and abuse. Commenting on Peck's case-study of postwar aluminum manufacturing inventions, Enos' study of petroleum refining, and Mueller's tracing of the origin of inventions underlying DuPont innovations, Arrow notes that patent royalties were trivial, so low that exploiting the inventions of others was not appreciably less profitable than exploiting one's own. The explanation presumably lies in the prevalence of monopsony and oligopsony or in the high cost of development which leaves little profit to squeeze. The conflicting implications of these references to market structure, as well as data about the 100 largest employers of research and development personnel since 1927, presented by Worley, are not resolved. On the contrary, Griliches concludes that there is no particular relation between market structure and inventive activity and that the subject has already received too much attention.

All of these points, however, weaken belief that patent statistics will ever prove as good in analyzing current fluctuations in technological advance as Schmookler finds them for the century before 1930. Sanders, Gilfillan, and Schmookler confirm that they have yet to be proven a valuable index of the secular trend. And when Schmookler finally reports that nowadays inventions in patentable form generally come from the development phase while central ideas come from basic research (p. 45), the notion of inventive activity as the contriving of things patentable must be seen as a research tool with a dull edge.

Little agreement exists about the manner in which the creation of technological knowledge should henceforth be subdivided. Schmookler finds that much applied research, far from being product- or process-specific, is really "basic" in the sense of illuminating whole classes of natural and industrial phenomena. "Pure research" would be practically indistinguishable from such activities, but being primarily motivated by the desire for knowledge, it would be an exogenous variable in economic development. Robert Merrill suggests the distinctions of "technically justified science" and "exploratory science-invention" as serviceable (p. 417). Merrill follows this classification with a deft analysis of pulls on the direction of research by nonmarket fac-

tors in academic science, engineering, and medicine, and in government agricultural research.

To some authors putting the acquisition of knowledge into the "economic cosmogony," as Siegel puts it, needs but a dab of analytical improvisation: knowledge, like any other commodity, must be extracted, processed, stored, maintained, and distributed. The first part of Machlup's account of the supply of inventors and inventions fits the supply of trappers and pelt just as well. Brozen sees research and development expenditures increasing at a decreasing rate as underinvestment is eliminated in high-research high-return industries, and equilibrium is approached. With a ritually correct multiple regression analysis of eighteen chemical and five drug manufacturers, Minasian shows that during 1947-57 research and development led to higher productivity and most likely, profitability. A minor difficulty conceded by Minasian is that the higher productivity measure of these firms may partly reflect their monopolistic achievements. Mansfield's calculations, moreover, indicate that in certain (perhaps the same?) chemical companies research and development expenditures are partly a function of expected sales, which could un-hinge Minasian's conclusion a bit more.

Two of the complications stressed by Arrow, external economies in production and the negligible social cost of using knowledge, need no methodological pioneering. In the presence of increasing returns, trying to avoid underproduction of knowledge through greater appropriability (a stronger patent system) means underutilization in both research and application. Machlup, however, thinks underproduction may be overstressed. In a few incisive pages (pp. 157-67) he suggests that in a given period the stock of knowledge and the problems to be solved are like fixed factors of production to which variable factors cannot be applied indefinitely without diminishing returns. Moreover, the problem-solving results of one period may conceivably more than offset concurrent problem-raising and knowledge-increasing effects in setting the agenda (the fixed factors) for the next period.

Fellner, similarly, finds that his usual economic tools can handle the problem of whether knowledge acquisition responds to factor scarcities. It will not, as long as factors are hired in pure competition but may under the "quasi-monopsonistic" conditions which are "less rare than is commonly believed" (p. 183). But as Nelson points out in his skillful introduction, Fellner's analysis implies that research directors can predict what kinds of production functions lie ahead. The papers by Rubenstein and Cherington indicate that neither in the large, decentralized firm nor in a government department is research pursued with the hope of such a high order of predictability.

On the contrary, seeking knowledge is almost synonymous with removing uncertainty. The management of uncertainty must be central to the economics of research: who will inquire if uncertainty is not aroused first? Four papers by Marshall and Meckling, Klein, Marschak, and Nelson (all associated with the RAND Corporation at the time) turn to this problem. They look "deeply at the insides of the black box—at the R and D process itself." Two examine weapons research for the Air Force, and two look at Bell Tele-

phone Laboratories operations, the development of a microwave relay communications system and the invention of the transistor. Surprising inferences and remarkable observations flow abundantly out of the black box. Uncertainties are great but indivisibilities in learning are not; hence "very modest expenditures can buy a considerable amount of information," and optimum resource allocation in research means parallel efforts reduced according to "sequential strategy" with no aim at a "predetermined optimal point" (Klein, pp. 488-96).

When one finds economists discussing decision strategy for handling information under conditions of uncertainty, one momentarily wonders whether the science of knowledge acquisition is not domesticating economics, instead of the reverse. But perhaps, as in a marriage, who is domesticating whom depends on which partner one asks.

With 23 papers at hand, I have not mentioned the salient points of most, nor the minor flaws of some. But final compliments are in order for the editors who were clearly uninhibited in removing duplicate coverage and unneeded comments, while allowing prepared and inspired discussants full swing.

W. PAUL STRASSMANN

Michigan State University

Factors in Economic Development. By A. K. CAIRNCROSS. London: George Allen & Unwin Ltd., 1962. Pp. 346. 35 s.

Economic Development in Perspective. By JOHN K. GALBRAITH. Cambridge: Harvard University Press, 1962. Pp. vi, 74. \$2.50.

These books are of particular interest as a reflection of a change in the mood of development thought. Until recently it would have been exceptional to question the importance of capital accumulation, the contribution of foreign aid, the value of industrialization, or the need for development planning. Now, however, a reaction has set in against the earlier orthodoxy. Both of these books support this reaction by arguing against a too easy interpretation of the development task.

Cairncross' volume is a collection of "essays, guesses and addresses," most of which have been published previously but are not readily accessible. Though wide-ranging and varied in approach, the score of articles and essays relate to three basic topics: investment and technical progress, international trade and development, and administration and planning. He wisely shies away from any one systematic theory of economic development or any specific strategy that might be followed by governments trying to force the pace of development. Instead, in a more fundamental fashion, he reminds us—by the very multiplicity of the factors that he considers—of the many facets to economic development, the variety of possible approaches to it, and the complexity of the elements by which it is governed. All this is sound economic reasoning placed in the widest context; it provides a healthy antidote to much of the development literature of earlier years which oversimplified the process of development and treated it as a mechanical or merely quantitative affair. From this volume, one will acquire no new gadgets of analysis, the latest elements of expertise, or simple recipes for development,

but he will more readily appreciate that the accelerated development of an economy cannot be separated from the development of a people and the development of a society—that the process is qualitative, involving changes in techniques, attitudes, and institutions.

In several basic chapters that assess the contribution of capital accumulation, Cairncross makes a strong case against the common view that capital exercises a predominant influence on development. He puts most emphasis on innovation in its widest sense, and argues the need to study far more attentively the social and economic forces to which innovation responds: not just scientific research but the incentives to seek out and employ new knowledge at the risk of loss. A major consideration is that technical progress operates largely in independence of capital accumulation and that capital is needed, not in order to allow innovations to be made but in order to consolidate the improvement in income that innovation brings about. The experiences of development planning in practice tend to confirm Cairncross' conclusions that, on the whole, there is a greater danger that the importance of capital in relation to economic progress will be exaggerated than that it will be underrated.

The chapters on the influence of international trade on development are also especially noteworthy. In examining patterns of trade and development, Cairncross provides several penetrating arguments against the extreme view, such as Myrdal's, that international trade operates as a mechanism of international inequality, and also against the more moderate view, such as Nurkse's,⁶ that the nineteenth century "engine of growth" through foreign trade cannot now operate sufficiently powerfully to allow primary producing countries to make full use of their expanding resources without a special effort to develop their domestic markets. Against such a pessimistic attitude, Cairncross emphasizes the importance and the uniqueness of the contribution that foreign trade can make to economic development.

The only disappointing section of the book is that on administration and planning. Although this part contains an illuminating discussion of the role of an economic adviser and an analysis of the uses and abuses of production programs, it may appear rather old-fashioned to the practitioner of development programming. It touches only tangentially on the major problems involved in delimiting the scope of a development plan and using the techniques of development programming.

Notwithstanding the failure to come to grips with the central issues of development planning, the discussion throughout this book is of the highest quality. Few books can approach it for clarity, moderation, and balance in analyzing the fundamental factors in economic development.

Gailbrath's book is thin reading for the academic economist, but it is nonetheless of considerable interest because of the author's position and the fact that the contents were originally presented in five public lectures in India. Comments are offered on the experience of the past decade of development, the theory of development planning, the role of education as an investment, and the use of the corporation as the principal instrument of industrial production.

At the outset, Galbraith criticizes the current discussion of economic development for mistaking parts of the problem for the whole. As a result, he submits that "we have probably wasted a good deal of time and effort doing things which were right in themselves but which made little or no contribution to progress because they were done in an environment which was inconsistent with advance" (pp. 5-6).

From this standpoint, Galbraith presents his major thesis: capital and technical knowledge are of only secondary significance compared with the primary requirements of effective government, education, and social justice. It is the lack of these that is of critical importance as a limit to advance in many countries, and until these barriers are removed little will come from capital investment and technical assistance. "While plans may be big on paper they will be small in result" (p. 10).

It follows, according to Galbraith, that in the early stages of development it is inappropriate to engage in detailed planning of investment; instead, the prior task is to lay the administrative, social, and educational groundwork for advance. It is acknowledged that India has had sufficient advancement so that capital and technical knowledge have become limiting factors, and India does have the capacity to engage in the complex planning of investment allocation. There is, however, the distinct possibility that capital provided to other countries that are not in such a relatively sophisticated stage of development will be wasted. We are warned that "we could make no more serious mistake than to imagine that the kind of planning that is done by India or Pakistan is essential for nations in all stages of development. In earlier stages it is neither necessary nor possible" (p. 16).

What Galbraith has to say may not be what the developing countries would like to hear, and it may be criticized as being too much a counsel of perfection. But many of his observations should be salutary in countering the tendency for poor countries to borrow at too high a level and to engage prematurely in comprehensive planning.

GERALD M. MEIER

Wesleyan University

Économie du développement. By ELIAS GANNAGÉ. Paris: Presses Universitaires de France, 1962. Pp. xi, 352. NF 24.

Professor Gannagé's study of economic development is a synthesis of both English and French contributions to the theoretical side of the subject. It is intended as a text for French-speaking university students. It provides an accurate, well-organized review of the field. Its major limitation is that it mirrors rather than resolves the basic contradictions in development theory, clinging by one set of fingertips to principles of allocative efficiency in a context of scarce inputs while trying with the other hand to build a case for the most Hirschmanesque methods of activating presumably plentiful latent resources.

The three sections of the book treat respectively the nature of underdevelopment, "vicious circles," and possible routes to development. The first section summarizes the main qualitative characteristics of underdevelopment

familiar in the literature, presents a minimum of statistical data accompanied by a case against reliance on any quantitative approach, and offers a careful definition in terms of structural dualism. The method enables the author to stress his fundamental distinction between "growth" as measured by statistical data and "development" in the sense of transformation of economic and social structures toward change and flexibility.

The section titled "Vicious Circles" draws its basic ideas from Nurkse but amends and clarifies Nurkse's suggestions most successfully. Gannagé's circles concern population pressure, capital and saving, income distribution, and international trade. The discussion of capital is oriented to a conclusion that the problem of stimulating investment demand is much more important than any concern with the adequacy of saving. With respect to arguments in favor of concentration of income to encourage saving he is, consistently with the preceding, highly reserved. He argues that inequality in underdeveloped countries is often linked to special privileges of social groups with little interest in productive investment, and that extreme inequality provokes both social tension and recourse to authoritarian controls. The discussion of international trade leaves room for almost any conclusion one prefers: frequent references to the desirability of protection to encourage domestic investment are approximately balanced by recognition that trade stimulates new ideas, provides an escape from Nurkse's problem of narrow markets, and may help induce structural change.

The final section on routes to development is very close to Hirschman. It is singularly lacking in the organized critical assessment applied in the preceding sections. The author's stress on promoting action rather than on economizing scarce resources leads him to argue in favor of machine-oriented capital-intensive techniques even in conditions of surplus labor, to reject the criterion of marginal social benefit in project assessment, and in general to propose that investment programs be designed in terms of the degree of disequilibrium they will create instead of the income they may directly produce. Hirschman's glittering insights are faithfully transmitted, without the limiting principles they so urgently require. The author's conclusion that efficient resource allocation is in any case less important than rapid structural adjustment is surely defensible, but the point serves as an escape hatch rather than a resolution.

For the French-speaking students for whom this book is intended, it provides a good review of a confused field. For those to whom English is accessible, its main interest may be that it provides a fine opportunity to examine the "structural" approach dominant in French studies of development.

JOHN SHEAHAN

Williams College

The National Income of Communist China. By ALEXANDER ECKSTEIN, Y. C. YIN, AND HELEN YIN. New York: Free Press of Glencoe, 1961. Pp. 215. \$6.75.

As economic studies on Communist China have become somewhat more fashionable in this country since the officially much vaunted "Great Leap"

of the Chinese economy in 1958, an increasing—but still woe—flow of literature in this field may now be expected even though the “Great Leap” itself has by now proved to be partly illusory and has been followed by a “Great Slide.” The present research monograph is an interlimited addition to this flow.

Apart from two introductory chapters, which provide the methodological setting, the main body of this volume consists of a chapter on the sectoral and aggregative estimates of Communist China income in 1952 and another chapter on the economic implications of these estimates, including very brief discussions on such topics as the use of resources, international comparisons, and problems of valuing such comparisons. Thus, while the title of the monograph gives the impression that it is a discussion of China's national income for a period of years, the substance is actually restricted to the year 1952. Consequently, one cannot expect to derive from this study any basis for a prediction on the prospects of Communist China. Nor is there any attempt to discuss the genesis and débâcle of the “Great Leap” which points to the “discontinuities” in Chinese economic development. Nevertheless, the reader may find the estimates for the year 1952 interesting reading, especially in comparison with estimates by William Hollister, T. C. Liu, and others.

One wonders whether it is really possible to limit treatment to the year 1952 without a much more substantial discussion of the historical background before and after 1952. It is unfortunate that, in the face of the rapidly changing situation in China, the author did not have information on the situation since 1959, which would have altered his brief description of the development. It is also a moot question whether the sacrifice in time span covered has been adequately compensated by the firmness of the Chinese economic structure on which attention is supposedly focused.

A number of detailed questions may also be raised. For instance, the 1952 crop production data are accepted without any serious question of their possible undervaluation; the structure of wages is assumed to be more “rational” than that of other factor prices without a more detailed discussion of the matter; discussion on such topics as the cost of living, overseas remittances, and many others is painfully brief. Within the minor points, it would seem that the author has found it difficult to make an exceedingly large number of assumptions, some of which are less arbitrary and sweeping than those other students, whom he criticizes, have had to make. This is almost inevitable in view of the scanty knowledge about the Chinese economy, but it would be wise for us to bear the point in mind if allowances are to be made.

Three points which emerge from the study offer the interesting general topics for challenging research: (1) shift of the base year for the Chinese economy of the pre-plan period from 1952 to perhaps an average of 1952-54, in view of the contention that the implementation of the first five-year plan as a national plan began only in 1953; (2) evaluation of the Chinese national product by adopting the criterion of final power as a measure of the final product; and (3) at a c

the construction of sectoral conversion rates between the *yuan* and other currencies for such sectors as consumers' goods, producers' goods, manufactures, etc. Eckstein hinted at the first two points, but did not follow through, while preliminary conversion rates for the agricultural sector only were constructed in one of the appendices. These are interesting problems which deserve much more intensive investigation.

YUAN-LI WU

University of San Francisco

The Soviet Economy: Structure, Principles, Problems. By NICOLAS SPULBER. New York: W. W. Norton and Co., Inc., 1962. Pp. xiii, 311. \$5.95.

This book is a concise discussion of the main features of the Soviet economic system which focuses on the principles and operation of the Soviet "model" of central planning. The treatment is analytical, rather than descriptive, and draws upon and summarizes principal recent literature on the various aspects of the Soviet economy. Because of its approach and its relatively short length, the book is suitable for courses in comparative economic systems as well as for courses in Soviet economics. Students with good preparation in economics will find it on the whole challenging but not unduly difficult. Teachers who are not specialists on the Soviet economy will undoubtedly learn from the book themselves.

The 15 chapters of the book are grouped into 5 main parts. The first deals with the nature of the national economic plan and the techniques used in its construction and execution. The second part examines the organization and operation of industry, agriculture, trade, and the labor force. The third part includes discussions of national income concepts and measurements and of the monetary and banking and fiscal systems. In the fourth part, Western and Soviet Bloc theories on economic calculation, pricing, and resource allocation under socialism are examined. The final part includes a chapter on intrabloc trade and one on economic competition between the Soviet Union and the United States.

The book has a number of features which will appeal to many readers and teachers considering it for adoption. One of these is its summary and synthesis of the extensive body of literature on various aspects of the Soviet economy which has appeared in journals and monographs in the last decade. The treatments of the labor force and of national-income and industrial-production measurements are examples. Also, the effort to develop a model of socialist central planning applicable not only to the Soviet Union but also, with appropriate modifications, to the rest of the Soviet Bloc provides a convenient and helpful theoretical framework for the study of the Soviet economy. In his treatment of the various topics, the author endeavors to apply the concepts and tools of contemporary economic theory to the analysis of Soviet economic planning and economic policy. Thus the discussion of economic calculation in the Soviet economy is preceded by a review of the debate among Western economists during the period between the two World Wars on the possibility and methods of rational allocation in socialism.

Some aspects of the book, however, will be less satisfying to many readers

As a result of the effort to present a comprehensive but concise discussion of the Soviet economy, the treatment of a number of topics is too brief and condensed to be clear to the average reader lacking previous knowledge of the subject. This is true, for instance, in the treatment of input-output and activity analysis (pp. 17-21) and the Marxian two-sector economic model (pp. 131-34). Moreover, the author's practice of not citing in footnotes the sources of his data and references to the authorities and studies mentioned in the text does not aid the reader in looking elsewhere for clarification. Although an extensive bibliography is provided at the end of the book, it is extremely difficult for the reader to identify in the bibliography the sources for statements and references in the text.

The coverage of the book will also not be completely satisfactory to some users. In his effort to present a model of "mature" Soviet socialist central planning, the author has excluded specific discussion of the historical path of Soviet economic development and the geographical and ideological factors affecting it. Although there are some references, at various points, to historical and ideological aspects, they are not emphasized. The discussion of foreign economic relations in Chapter 14 deals exclusively with Soviet Bloc trade, neglecting Soviet economic relations with the less developed countries and with the industrialized capitalist countries.

While this book offers a concise and sophisticated treatment of the Soviet economic model, its strengths in this regard also will cause students and teachers lacking previous familiarity with the Soviet economy some difficulties in the use of the book. Some of these problems can, however, be overcome by the use of journal articles and collections of readings to supplement the book by providing more extensive and simpler explanations on topics covered in the book, as well as material on other topics.

MORRIS BORNSTEIN

University of Michigan

Economies of the World Today—Their Organization, Development, and Performance. By CLAIR WILCOX, WALLIS D. WEATHERFORD, JR. AND HOLLAND HUNTER. New York: Harcourt Brace and World, Inc., 1962. Pp. vii, 148. Paper, \$1.85.

This book examines the main features of the economies of the Soviet Union, Communist China, India, Great Britain, and the United States. It has been written to be used as supplementary material in the introductory economics course and should prove to be a highly useful addition. The amount of time spent on comparative forms of economic organization in the introductory course is ordinarily quite limited. Authors of the leading texts typically add a short chapter at the end of their voluminous texts on this subject. Frequently, this chapter is little more than a sketchy treatment of Marxian ideas, plus some descriptive material on the Soviet economy, fascism, and British socialism. The very heavy emphasis given in the texts to the private enterprise market economy, with extensive theoretical treatment of its main features, can create a lopsided view of the breadth and complexity of economic organization. In view of the vast changes that have occurred in the

recent past, a broader perspective is certainly needed if the beginning course is to fulfill its function as an essential part of the liberal arts curriculum.

The introductory chapter discusses terminology and explores the meaning of economic individualism, economic collectivism, and various mixtures of these as predominant characteristics of the different economies. Concepts of economic growth and development are then given major attention, supported with statistical data and charts showing the per capita gross national product for most of the nations of the world in 1961, and the rates of economic growth of many of the principal countries in the 1950's. A theoretical analysis is made of the factors that influence these rates of growth. Finally, the authors select five criteria to evaluate the performance of an economy. These are Plenty (standard of living), Economic Freedom (to choose an occupation, to spend, save, invest, etc.), Justice (equality of economic opportunity), Personal Security, and Growth. The relationship between the priority given any particular goal in a given economy and the nation's political, social, and cultural institutions is emphasized.

Each chapter devoted to a specific economy gives a short historical background sketch, and indicates the stage of economic development reached. The Soviet Union is depicted as a relatively mature, thoroughly collectivized economy with authoritarian political control. The central role of over-all planning, the radically different functions performed by prices in the system, the problem of incentives, and the problem of the degree of economic freedom the system can permit shows how the authoritarian goals of the political elite structure the economic organization. Communist China, although similar to the Soviet economy in its collectivist, authoritarian nature has developed its own methods of transforming itself from an agricultural economy to an industrialized one. The creation of the commune, a new social and economic unit displacing the traditional family unit, and the widespread use of labor-intensive technology are unique features of the Chinese economy. The enormity of the revolution that is being attempted in the political, cultural, and economic life of this nation of more than 700 million people, is something that few students are aware of. While its growth rate has been spectacular, the harsh human costs have been very great.

India presents a contrast to Communist China in its efforts to achieve similar economic goals. Reliance has been placed on economic individualism plus an increasing degree of public enterprise and planning. Although the human costs are far less than those imposed on the Chinese, the pace of growth is very slow. India's rapidly growing population and relatively limited resources, and its religious and social traditions provide great obstacles to economic progress. Over-all planning by public authorities for development has encountered a host of difficulties, and without considerable aid from other countries, the forward momentum achieved to date may be lost.

Great Britain provides an example of a mature, relatively affluent society that has depended largely on the operation of free market forces to guide its economic life. The high priority given to the goals of "welfare" and "security" have brought more and more government modification of the free market economy. The British social security system is evaluated, particularly the

provision made for medical services for all. The conflict between "welfare" and "growth" are examined in the context of Britain's dependence on foreign trade and its chronic concern over balance of payments problems. Finally, the United States is appraised as the leading economy that is more thoroughly individualistic than any of the others. Nevertheless, the competitive discipline of the free market economy is blunted by the rise of huge corporations, great labor unions, and large public corporations. While the most affluent of all economies, its rate relative to the Soviet economy indicates that if the disparity continues, the United States can be surpassed in per capita output.

The compact, well-organized fund of up-to-date information in this book will be of value in a number of economics courses, but is especially well written for the introductory course. In their preface the authors state that "they have long felt that the introductory course in economics should culminate in a comparison of several different economies. They felt that the student would thus obtain a clearer perspective of his own economic system and the principles and problems he has studied would take on a new meaning when viewed in relation to economies of different kinds." The reader will find a hearty accord with this viewpoint. The comparative study of different economies will help to integrate the various topics treated separately in the introductory course. The student will find that this grasp of the monetary system, the price system, the role of saving and investment, and the structure of a market economy with other economies provides a highly useful background for absorption of the materials in this book. His understanding of the scope of economics should be substantially broadened and deepened. The brief bibliographies suggested as further reading at the end of each chapter provide a ready means for further exploration of the issues.

The Share of Top Wealth-Holders in National Wealth, 1922-56

J. LAMPMAN. National Bureau of Economic Research, General Series, No. 74. Princeton: Princeton University Press, 1962. Pp. 100. \$6.50.

This book presents annual estimates of the wealth holdings of the top 1 per cent of the population if they had died during the year, would have left estates large enough to require filing a federal estate tax return. The data from which the estimates have been derived are the estate tax returns filed. The minimum requirement currently is \$60,000, but it varied from \$40,000 to \$100,000 during the period analyzed. Knowing the age distribution of persons with wealth and the percentages in each age group who had wealth holdings of various sizes, and knowing the age distribution of the population as a whole, one could construct a hypothetical wealth distribution for the population as a whole—as given age, the probability of death is independent of wealth. Of course, the entire distribution cannot be estimated from the data analyzed in

However, this analysis of the wealth holdings of those with the largest amounts of net assets complements other studies, which generally have been based on samples containing very small numbers of the largest wealth holders.

The estimation procedure—previously used by Mendershausen in estimating a part of the U.S. wealth distribution and by research workers in Great Britain, Italy, the Netherlands and New Zealand—together with the sources of data, are described in detail in Chapters 2 and 3. Chapter 4 describes such estimated joint distributions as those of wealth, age, and sex; wealth, sex and marital status; and wealth and residence for the year 1953. Chapter 5 presents estimates of the amounts of various classes of assets held according to the size of the estate and according to age for 1953 and by years for all estates, 1922-54. Chapters 6 and 7 deal with the changes in the shares of total wealth held by the top wealth-holders over the period analyzed. An appendix presents much of the underlying data and estimates, and there are also appendices relating to the effects of price changes and to forecasting the number of estate tax returns.

Among the findings of the study are: (1) The top wealth-holders are also in the upper age groups, the median age being 54 years. (2) Women top wealth-holders increased in relative importance during the period studied. This phenomenon is explainable partly by the increase in the relative population in the community-property states and the higher survival rate of wives. Thus, if a man holding property in community with his wife dies before his wife, only half the property acquired after marriage is reported for estate tax purposes. When the wife dies, the other one-half plus the inheritance is reported. (3) There was a pronounced decline between 1929 and 1949 in the percentage of personal wealth held by the top wealth-holders. Between 1949 and 1956 this trend was reversed. This decrease in inequality in the wealth distribution between 1929 and 1949 is attributed to decreased inequality in the income distribution and the consequent decrease in the inequality of the saving distribution. No explanation for the reversal since 1949 is offered.

Since the estimates of wealth for the population as a whole as well as for the top wealth-holders are both subject to error, one should know something about the error distributions before he evaluates statements about the time trend of wealth inequality—as measured by the shares held by the top wealth-holders. No confidence intervals for either of the sets of estimates are presented. However, the study's importance need not be interpreted solely in terms of what it can say about the time path of wealth inequality.

O. H. BROWNLEE

University of Minnesota

An Introduction to Econometrics. By LAWRENCE R. KLEIN. Englewood Cliffs: Prentice-Hall, 1962. Pp. viii, 280. \$7.50.

Lawrence Klein has now written a nontechnical introduction to econometrics, intended to preface the serious study of formal methods, and I believe the book must be regarded a major pedagogical success. His procedure is to introduce the student to econometrics by considering a sample of the best applied

econometric studies in each of several subject-matter areas. The areas included, with the names of some major investigators whose researches are discussed, are: demand analysis (H. Schultz, K. Fox, H. Houthakker); production and cost analysis (P. Douglas, J. Dean, W. Leontieff); distribution of income and wealth (V. Pareto, H. Lydall, F. Adams); models of growth and cycles (M. Friedman, L. Klein, R. Solow, J. Tinbergen, F. and I. Adelman).

In the discussion of each subject, a certain amount of relevant economic theory is presented, the investigator's statistical methods and results are discussed, and relevant econometric problems are outlined. By the end of the book the reader has reviewed a considerable amount of basic economic theory and statistical methods and received a lucid and thoughtful introduction to almost all the major problems—such as identification, multicollinearity and autocorrelated residuals—with which econometrics deals. Throughout, the emphasis is on the explanation of the relevance of problems to substantive research rather than on the presentation of formal methods to deal with the problems. The purpose is to whet the reader's appetite for further, more systematic study of methods.

Although this is obviously a desirable approach, it is very difficult to bring off. There are temptations to include too much, to include studies whose understanding requires extensive knowledge of specialized areas of economics or statistics, to make the presentation uneven, and to give the reader the impression that econometrics is a miscellaneous collection of unrelated studies. Klein has avoided these pitfalls and others. He has not attempted to be comprehensive or completely up-to-date in his choice of studies, but has carefully chosen investigations that illustrate important economic and statistical insights, and whose main outlines can be understood at a rather elementary level.

This book should finally put to rest the notion, still held by some economists who should know better, that econometrics consists in the mechanical application of standard mathematical and statistical formulas to the exclusion of nonquantifiable considerations. Good econometric research, like all good empirical research in economics, requires deep understanding of relevant institutions, insight, judgment, flexibility, and a certain amount of sheer opportunism. The triumph of Klein's book is that he brings out both the nonmechanical aspects that give uniqueness to the investigations and the careful use of theory and statistical inference that give them unity.

Although Klein has been very careful to keep the book at a uniform level of difficulty, it will not be easy reading for the intended audience. Prerequisites should include the material covered in undergraduate courses in micro- and macrotheory and statistics (including regression analysis). In addition, the student must be able to understand elementary algebraic notation and manipulations. Students who are technically-minded enough to be willing to follow the argument will probably have had a course in calculus, though it is not necessary. Even with these prerequisites, many students will find parts of the book tough going. However, the required intellectual investment will yield high returns. The social dividend would be increased if every graduate stu-

dent in economics would read this book even if he pursues his study in econometrics no further.

EDWIN S. MILLS

Economic Systems; Planning and Reform; Cooperation

Rachunek ekonomiczny w socjalizmie (Economic Calculation under Socialism). By JANUSZ G. ZIELINSKI. Warsaw: Panstwowe Wydawnictwo Naukowe, 1961. Pp. 226. Zlotys 18.

The author defines economic calculation as measurement of costs and benefits resulting from alternative decisions on resource allocation. In a planned, socialist economy the use of a "market-type" calculation is advocated, scarcity prices (which include interest and rent charges) serving as indices of terms on which alternatives are offered. Two variants are considered, depending on whether the product- and input-mix of each firm are selected by its manager (Oskar Lange's well-known "competitive solution") or by the Central Planning Board itself ("the shadow-market solution" presumably involving the use of electronic computers). In either case resources are allocated in accordance with prices reflecting relative scarcities. The use of such price parameters by the planners is held compatible with a thorough-going centralization of the decision-making process. Either variant of the market-type calculation is held preferable to the "direct" method actually employed in socialist (Soviet-type) economies, under which inputs and outputs are centrally planned, coordinated, and allocated in physical terms: "allocation decisions result directly from technological relationships . . . and not from cost-price relationships" (p. 89). The major shortcoming of the direct method is that it treats production coefficients as structural constants and therefore lacks any criterion for the choice of production methods.

Zielinski does not deal with the interesting question, how have Soviet-type economies managed to function and to revolutionize their production functions in the absence of such a criterion? In this reviewer's opinion, imports of ready-made U.S. production methods into the USSR and then of Soviet ones into countries of East-Central Europe may have provided a partial substitute for this deficiency in the direct economic calculation in many crucial investment decisions. Needless to say, such imitative practices may have led to nonoptimal solutions when the countries concerned had widely different scarcity relationships.

The author inquires next about the applicability of the tools of welfare economics for the evaluation of economic policies under socialism. His treatment is selective. Such criteria as Pareto's optimum or the principle of compensation are viewed as being of little practical use. On the other hand, the optimum conditions of resource allocation are believed to be useful and applicable to any economic system. There follows an incisive, illuminating discussion of the role of consumers' sovereignty in a planned, socialist economy. Zielinski defends "the Postulate of Limited Consumers' Sovereignty." "While

planners' preferences take precedence over consumers' preferences, especially in the domain of collective consumption, it is in the planners' own interest to take account of consumers' preferences in all cases where there is no adequate reason for not doing so" (p. 139). The author agrees with Abram Bergson that there exist substantial ranges of choice within which the Central Planning Board is indifferent as to resource allocation and emphasizes the enormous number of choices within such areas in which "the Central Planning Board's only preference is to do . . . whatever consumers want it to do" (p. 169). Zielinski points out that consumers' sovereignty should extend not only to the output of consumers' goods industries but also to induced investment in such industries. He does not consider that in exercising these rights consumers might affect the rate of investment and of economic growth and thus infringe upon the jealously guarded areas in which the planners have very definite preferences.

It is interesting to note that the Polish economist emphasizes the theoretical and practical significance of consumers' sovereignty and presents a persuasive plea for its partial restoration in planned socialist economies at the time when some Western scholars criticize the doctrine in question as being incomplete, ambiguous, and lacking theoretical refinement.¹ The proper approach may lie somewhere between "the [Western] economist's excessive preoccupation with consumers' choice in the market" mentioned by Scitovsky (*loc. cit.*, p. 262), and the East European planners' "prejudice against obeying consumers' preferences" described by Zielinski (p. 140).

Perhaps the time has come to do what J. M. Clark once did for the concept of competition and to formulate a doctrine of Workable Consumers' Sovereignty, with suitable variants applicable to different economic systems. An English translation of Zielinski's thoughtful and thought-provoking study might greatly assist us in this challenging task.

Business Fluctuations

Postwar Cycles in Manufacturers' Inventories. By THOMAS M. STANBACK, JR. Studies in Business Cycles, No. 11. Princeton; Princeton University Press for National Bureau of Economic Research, 1962. Pp. 146. \$2.00.

This short book is in effect an extension of Moses Abramovitz's pioneer work, *Inventories and Business Cycles, with Special Reference to Manufacturers' Inventories*, published by the National Bureau in 1950. Abramovitz dealt with the interwar years; Stanback carries the study through the 1947-56 period.

A principal relationship which Abramovitz isolated seems to be confirmed by later data, namely the differing impact of nonfarm inventory changes (mainly changes in manufacturers' inventory) upon GNP as between con-

tractions and expansions. The relation between inventory disinvestment and GNP decline is noted as particularly strong; and the fact that there has been a postwar reduction in size of inventories, in relation to output and sales, does not seem to have disturbed this association. Thus Stanback's observation (p. 5), in a review of both interwar and postwar periods: "Measured on the basis of annual data, the changes [in nonfarm inventory] are found to have accounted for at least 42 percent of the decline in national product in every business cycle contraction except that of 1929-32." The relation is of lesser magnitude for expansions. Stanback agrees with Abramovitz that the typically longer duration of the expansion period accounts for much of this; he thinks it is also (in the postwar period) because inventory turning-points have run ahead of GNP, so that the impact of inventory investment is in part unobserved when a GNP-trough-to-GNP-peak period is used.

It seems worth noting that this percentage relation between change in inventory and change in GNP varies considerably, both in contractions and expansions. The figure is sometimes disconcertingly high. In the 1948-49 contraction, using annual data, inventory disinvestment is recorded as 1,400 per cent of the change in GNP. The use of quarterly data (which Stanback had available for the postwar years, in contrast to the annual figures which Abramovitz had to use) gets this figure down to 195 per cent. Even the percentages based on quarterly data vary substantially. It is interesting, though doubtless coincidental, that postwar contraction-period percentages show a steady decline: 195 (1948-49), 62 (1953-54), and 35 (1957-58).

Any study of the relation between inventories and national income can consider the impact of inventory changes upon income, or else the impact of income changes upon inventory, or finally the interrelationship between the two. Stanback's discussion of the first of these topics (in part described above) is in Chapters 2 and 3. His final chapter (Chapter 8) considers the third—and most difficult—of these. It is an evaluation of Metzler's accelerator-multiplier inventory models, in the main a summary of the manifold problems involved in subjecting such models to quantitative test. In this short book the author does not undertake much analytic path-breaking with respect to inventory-income interrelationships, nor for that matter with respect to the impact of inventory changes upon income. Stanback's principal interest (in Chapters 4 through 7) is with the forces, changes in income and others, which seem to bear upon manufacturers' inventory levels.

In this exploration, Stanback agrees with Abramovitz that total manufacturers' inventory movements are best considered as an aggregate of (at least) three subtotal series: purchased materials, goods in process, and finished good inventories. The analysis is conducted accordingly. In the outcome, some of Abramovitz's tentative conclusions are qualified; but none is really overthrown.

Stanback is particularly interested in the evident tendency for turns in purchased-material inventory investment (notably in durable-goods industries) to lead business-cycle turns over the period studied. These figures may be in some small degree at odds with Abramovitz's initial assumption that the level of such inventories (and hence inventory investment) is primarily dictated

by the level of manufacturing activity, subject to some lag (of a determinate length) due to delays in materials delivery. Stanback sizes that the size and influence of unfilled-order backlogs may be the discrepancy. With output level unchanged, a decline in the order backlog may be considered a forewarning of recession and of the need to reduce inventory on hand. The evidence does not afford the prices of materials a particularly important role in determining inventory investment.

The availability of quarterly data for GNP and nonfarm inventory investment in the postwar years is evidently a considerable advantage for the economist as this. Stanback's task in estimating the relation of inventory turns to output and cyclical turns is considerably eased in contrast to that of Abramovitz, who was forced to work with annual data.

This is a careful and painstaking work. Yet one is left with the impression that the material to be handled is complex and difficult in the sense that the analytic structure for its interpretation is (and may remain) incomplete.

ROMNEY

Brandeis University

Money, Credit and Banking; Monetary Policy; Consumer Finance; Mortgage Credit

Money, Saving and Investment in English Economics, 1800-1850

CORRY. New York: St. Martin's Press, 1962. Pp. xi, 188. \$6.75.

Opinion on Bank Rate, 1822-60. By A. B. CRAMP. London: G. B. Cramp Ltd. The London School of Economics and Political Science, 1962. Pp. xi, 118. 25s.

By directing attention to the role of money in nineteenth-century economics and policy, B. A. Corry and A. B. Cramp focus on the central issues of that classical era. Oversaving, overinvestment, recurring monetary crises and occasional panics are standard references of the period. Cramp's book is an interesting essay on the history of monetary policy. Corry's book makes a contribution to the history of unorthodox thought.

Cramp's leading question is how the Bank rate operated before the development of a conscious policy of open-market operations to make it effective. Opinions are drawn from parliamentary committees, pamphlet literature and contemporary periodicals, especially *The Economist* and *The Bankers*. Among the individuals whose opinions feature in the discussion are Horsley Palmer, S. J. Lloyd (Lord Overstone), Walter Bagehot, John Lubbock, J. W. Gilbart and Thomas Tooke.

Among the group which held the opinion that the Bank rate had little influence on the market rate of interest were Bank of England officials who contended that they could not establish, nor influence much, the market rate. Shades of McChesney Martin in our time! Cramp sagaciously points out this position by Bank officials to their reluctance to accept the responsibility for fixing the market rate of discount. Among a large

thought that the Bank rate did influence significantly the market rate of interest, Cramp finds the "confidence effect" rather than the "incentive effect" (Radcliffe Committee terminology) a more correct and a more widely held interpretation of the *modus operandi* of the Bank rate. In an age before the Bank of England acknowledged its responsibility as lender of last resort, Cramp believes businessmen and provincial bankers had good reason to run for cover whenever the Bank rate rose to betoken storm clouds. Cramp's interpretation is closer to the views expressed by Sayers than to the interpretations of Hawtrey and Elmer Wood, and Cramp's volume may be viewed as a complement to Sayers' *Central Banking after Bagehot* (1957).

Corry develops in some detail the theory of money, investment and savings of classical economics from Adam Smith to J. S. Mill, and finds that the classical economists had a more sophisticated and thorough treatment of money than is commonly believed. More interesting than the orthodox writers, but definitely inferior according to Corry, are the ideas concerning money, saving and investment of the unorthodox dissenters, including Lauderdale, Malthus, Chalmers, Thomas Attwood, William Spence, John Rooke, John Barton, John Lalor, John Fullarton, Thomas Joplin and William Blake. Despite some brilliant intuitions, however, these dissenters failed to destroy the logical foundations of classical macroeconomics. They assumed, along with the classicists, an equality of *ex-ante* savings and investment and failed to develop a multiplier theory. Hence none deserve to be classed as "early Keynesians."

Among the dissenters of the period, the one who most nearly anticipated Keynes was the relatively unknown John Lalor, author of *Money and Morals* (1852). Unlike the others, Lalor did recognize an *ex-ante* inequality of savings and investment and did develop a multiplier theory. However, he had no satisfactory theory of the rate of interest and therefore he also fell short of a claim to legitimate Keynesianism.

Corry does well to "discover" John Lalor, but why does he not mention contemporaries such as John Gray and John Francis Bray, whose ideas were closer to Keynes in important respects than were the writers he does discuss? Perhaps the answer lies in Corry's general philosophical orientation. While he largely avoids the broader issues of sociology of knowledge, enough slip is showing to reveal what is beneath the exterior garment. He expresses indignation toward those who interpret classical economics as an argument for *laissez-faire* policy. Instead he contends that the classical school's affinity for *laissez-faire* stemmed from classical theory, not the other way round. This position taken by Corry is more easily asserted than proved, and perhaps it reflects the philosophical position of his teacher, Lionel Robbins, whose *The Theory of Economic Policy in English Classical Political Economy* (1952) is cited as a model work.

Some peculiar conclusions flow from Corry's interpretation. John Stuart Mill is pictured as the arch-conservative of the classical theory of money, saving and investment, a position which seems dubious in the light of Mill's chapter on "Excess of Supply" in the *Principles*, where he comes close to throwing overboard the law of markets. A stronger case can be drawn, I believe,

for viewing Mill as the first of the theoreticians of the welfare state rather than the high priest of anti-interventionist classical *laissez-faire* economics.

Both Cramp and Corry are, in a sense, concerned with the antecedents of Keynes, and their works form part of a general rewriting of the history of economics which is following in the wake of the Keynesian Revolution. Unfortunately neither penetrates the real meaning of Keynes' monetary economy, in which money is a unique asset as the socially recognized form of private wealth. Cramp brushes against the problem of a monetary economy in discussing the confidence effect, which is associated with uncertainty concerning the conversion of other assets into cash.

My main criticism of Corry is not in the details of his analysis but in the broad picture he paints of the interplay between ideas and events. Readers are left with the impression that classical economics triumphed, and subsequently hardened into dogma, because it was intellectually superior to the theory of unorthodox dissenters; and that only a great intellectual tour de force by Keynes unshackled society from the tragic grip of an unwise noninterventionism which failed to develop planning for full employment. Such an interpretation is flattering to economic theorists, and to the classicists and Keynes in particular, but I frankly doubt that it accurately describes what happened in history.

DUDLEY DILLARD

University of Maryland

Money, Banking and Monetary Policy. By CLIFTON H. KREPS, JR. New York: The Ronald Press Co., 1962. Pp. iv, 607. \$7.50.

This money and banking principles text is divided into six parts, respectively occupying the proportionate space indicated: Money (9 per cent); Monetary Standards (14 per cent); The Banking System (13 per cent); Commercial Banking (26 per cent); Central Banking (21 per cent); and Monetary Policy (17 per cent). As the author's division of the field and apportionment of space suggest, the approach is subject-integrated and policy-oriented. The aim of the book is to develop in its readers an appreciation of the uses and limits of monetary-standard, banking, and monetary policies and a capacity to analyze monetary and banking policy problems of national economic significance.

Kreps has woven into his text a background of the economic, monetary, and banking theory necessary to facilitate an understanding of why and to what extent banks create money, as well as how they do it. In addition, to give the student a sensitivity to the policy usefulness of theory, the author analyzes the historical development of monetary and banking institutions and structure, commercial banking theories and practices, and the observable role of theory as a tool of central-bank policy.

Each of the 30 chapters is concluded with concise review questions and a number of citations of supplementary readings. A three-paged Appendix to Monetary Policy—on the background of the Commission on Money and Credit—completes the work.

The presentation strives to make explicit for the beginner much continuity

often left implicit for the initiated. For example, explanations are given of the significance of: leakages and offsets in the money end of the circular flow of exchange; the money-creating-and-destroying powers of the commercial banks exercised as a by-product of the profit motive; financial intermediary institutions as indirect influences on the volume of "effective money" via its income velocity factor; and the International Monetary Fund as a reflection of our "double" (internally "fiat" and externally "gold") monetary standard.

The gravitation of both content and narrative around commercial banking as a focus of interest does much to unify the presentation. In unfolding the subject, the author's preoccupation is more with integrating the material covered and orienting it to policy uses than with maximizing the number of topics included or describing financial institutions as such.

Kreps is a persuasive defender of the anti-inflation capabilities of monetary policy. He argues that financial intermediaries cannot by-pass the effectiveness of monetary policy if its restrictive pressure is tellingly applied against the power of these nonbank institutions to modify the supply of money. Along with the wider span of Federal Reserve (qualitative and quantitative) controls needed to plug up this velocity loophole, the author advocates upgrading the relative role of monetary policy—vis-à-vis debt management and fiscal policy—as an effective arm of aggregate public economic policy.

Some highlights of the work are the comprehensive picture of the U.S. monetary system and its derivation, the mature treatment of the international financial position of the United States, the probing consideration of the typicalness of the typical bank, and the functional handling of financial institutions.

It would be difficult to make substantial criticism of the book; but a purely negligible point which some readers may notice is Kreps's use of the phrase "secondary deposits" for the more usual—and, to this reviewer, more expressive—"derivative deposits." The author's nonencyclopediaic approach renders the work more useful as a review reference than as a bookshelf manual. The book is, however, a formidable addition to the textbook sector—and to the general literature—of the field. It is both cohesive and readable.

In fact, if—after exposure to this penetrating exposition of the subject—the student should by any chance fail to acquire a depth of perspective for understanding the monetary and banking policy problems with which our economy is constantly wrestling, the blame cannot be laid at the door of the author.

HOWARD S. GORDMAN

Georgia State College

Public Finance; Fiscal Policy

Tax Credits and Intergovernmental Fiscal Relations. By JAMES A. MAXWELL.
Washington: The Brookings Institution, 1962. Pp. xiv, 202. \$3.75.

Professor Maxwell in this book has once again displayed his command over a most complex and intricate area of public finance, that of the relationship

between the central government and state and local governmental units. But, partly because of its professional competence, the book has left this reviewer with a pessimistic appraisal of the prospects of working out a really desirable solution to the complex problems in this area, and perhaps even of defining what such a solution would be.

Maxwell's main concern, like that of others viewing this question in broad terms, is that in the United States the expenditures of state and local governments have outgrown the available sources of revenue in recent years. And more than this, a continued rapid expansion of expenditures seems called for in areas for which the states and localities have traditionally been allocated primary responsibility in our society—areas such as schools, roads, recreational facilities, utilities, and other similar public services. Opposed to this need for ever-increasing expenditures is the well-recognized fact that state and local revenue systems, depending heavily on inelastic revenue sources, are not geared to satisfy it. The almost inevitable result, barring some change in existing practices, is an unduly low level of expenditures on many of our most vital public services, and at the same time an inequitable distribution of the tax burden to finance those expenditures which are made.

There is nothing new in the statement of this dilemma. The contribution of the book is rather in its careful and systematic treatment of the devices which have been used in the United States, or which might be used, to resolve it. Attention is concentrated almost entirely on the fund-raising aspects of the problem; only one short but interesting chapter is devoted to federal grants (conditional or unconditional) as a means of restoring the balance between the revenue-raising capacity and the expenditure needs of the various levels of government in our federal system.

In the United States we have had experience with two major tax credits, a death tax credit since 1916 and an unemployment tax credit since 1935. A chapter is devoted to each of these credits, tracing their purpose as originally enacted, the course of their development, and the problems which have arisen in connection with them. In a broad sense, each accomplished its objective. The death tax credit established in 1916 successfully forestalled the efforts of certain states (Florida and Nevada) to attract wealthy residents away from other states by constitutional amendments forbidding their legislatures from enacting death taxes. Thus, the general use of death taxes by the states was not undermined by the "anarchistic" moves by a few states, to use Maxwell's adjective. Similarly, the unemployment tax credit was an effective device stimulating the individual states to enact unemployment compensation plans acceptable to the federal government.

Although in these broad terms these two major tax credits could be described as successful, Maxwell in his detailed discussion of them points out difficulties which have arisen with each of them. The death tax credit, for example, did not prevent states from enacting "death taxes which varied in type, definitions, rates, and exemptions, so that complexity and structural disorder became serious problems" (p. 159). Likewise, the unemployment tax credit has not resulted in a uniform rate of payroll tax and the elimination

of interstate competition. Rather, largely through the so-called merit-rating devices, a variety of rates (or tax bases) prevails, and the danger of interstate competition has reappeared. Maxwell's concluding judgment on the unemployment tax credit is that "in this its most ambitious use [the tax credit] has proved inflexible. Possibly, even probably, the credit was not the right technique to secure a good system of unemployment insurance for the long run" (p. 159).

The second portion of the book consists of an analytical discussion of the effects and desirability of other tax credits or similar devices for strengthening state and local revenue sources with which we have had little or no experience in the United States. A long chapter is devoted to individual income tax credits of various types. The closely related topic of the deductibility of state and local taxes is also examined at length. Finally, as noted earlier, a very brief discussion of federal grants is presented to round out the possible alternatives.

Although the second portion of the book contains more new material than the discussion of the death and unemployment tax credits, no attempt will be made here to summarize Maxwell's conclusions. A host of considerations of different dimensions have to be introduced, and any conclusions rest on the relative weight attached to these considerations plus the value judgments which the appraiser brings to the problem. Suffice it to say that the whole area of intergovernmental fiscal relations is one in which only the ignorant or the foolish would dare to propose simple, dogmatic solutions to the dilemma posed in the opening paragraphs of this review. For those so tempted, as for others interested in a scholarly and penetrating treatment of the many complexities presented by tax credits and other similar means of intergovernmental fiscal relations, this book is recommended.

Harvard University

Dividends Under the Income Tax. By DANIEL M. HOLLAND. NBER Fiscal Studies No. 7. Princeton: Princeton University Press for National Bureau of Economic Research, 1962. Pp. xvii, 189. \$4.50.

In this monograph, Professor Holland investigates four main questions: the size of dividends as a component of individual and taxable income, the dividend "gap," the tax liability resulting from dividends, and the differential taxation of corporate earnings resulting from the federal corporate profits tax and the federal individual income tax. The latter topic was explored in some detail in Holland's earlier study, *The Income Tax Burden of Stockholders*. These are questions to which quantitative answers can be given and Holland proceeds to do so carefully and imaginatively within the limitations of the available data.

Dividends taken alone are a small component of personal income amounting to less than five per cent of personal income and about the same of adjusted gross income in recent years. The dividend category has the distinction of being more unequally distributed than other forms, the 2 per cent of

dividend recipients having incomes of \$50,000 and over obtaining 36 per cent of reported dividends. The dividend "gap," a matter which has been given considerable attention because of efforts to introduce collection at the source, turns out to be, according to Holland's estimating procedures, in the neighborhood of \$1 billion in recent years or about 10 per cent of the presumably correct reportable figure. Considerable evidence exists that the underreporting occurs primarily in tax brackets under \$25,000—the very wealthy apparently being more concerned than the merely wealthy in keeping free of the clutches of the law. Of less interest is the specific tax liability attributable to dividends and to the built-in flexibility of this component. Those familiar with tax literature will not be surprised to learn that the present two federal income taxes overtax low-income stockholders and undertax high-income stockholders. This hoary piece of knowledge, however, seems incapable of penetrating the thinking of many Congressmen, journalists, and even economists.

Under the stimulus of a good question raised by Willard Thorp, Holland investigates the relation between the pay-out policy of corporations and the size of income-bracket stockholders. Thorp surmised that the tax laws might induce high-income stockholders to hold stock of corporations with low pay-outs, in search of large capital gains. On tax-incentive grounds, the surmise is reasonable; a high-income stockholder should prefer capital gains to equal dividends. Holland's high quality detective work leads to the interesting result of no significant relationship at all.

A critical theoretical question in Holland's work concerns the shifting and capitalization of the corporate income tax. Holland assumes that the tax is neither shifted nor capitalized, relying upon undisclosed authorities for this view. A systematic review of the literature might have been undertaken to provide a rational basis for the assumption. In my view, Holland is correct enough, provided that the corporate income tax is considered along with other taxes, namely the personal income tax. Those who claim that the tax is shifted have usually considered the tax in isolation, neglecting the fact that gains from other business forms considered alone are also taxed, embracing once again the "double-taxation fallacy."

Holland has not answered all the questions that need to be answered by evidence in connection with the combination of corporate and personal taxation. There is, for example, only fragmentary information about the extent of underreporting of total net gains, realized and unrealized, associated with security ownership, and the extent, if at all, corporations are taxing their stockholders by earnings retention. To learn more about such matters, reported corporate profits data will need close examination, including correction, if possible, for the distortions introduced by accelerated depreciation and various other inaccurate accounting procedures promoted by the income tax laws and regulations.

Holland has in this study prepared a solid piece of research which should prove useful to students of finance as well as those who merely wish to know more about the economic facts of life.

EARL R. ROLPH

University of California, Berkeley

The Financing of Economic Development. By SANTIKUMAR GHOSH. Calcutta: World Press, 1962. Pp. 100. Rs 6.50.

Deficit Financing and Capital Formation—The Pakistan Experience, 1951-1959. By PARVEZ HASAN. Karachi: The Institute of Development Economics, 1962. Pp. 97. Rs 5.

These two small volumes lead us through the frequently but still incompletely explored subject of finance and the process of economic growth. The first reviews the general problem with some special reference to India's five-year plans; the second is an excellent case-study of the Pakistan experience with deficit financing during the decade of the 'fifties.

Ghosh approaches the problem in the broadest terms: What financial policies might be used to mobilize resources for capital formation and introduction of improved techniques? He devotes one chapter each to credit creation and inflation, taxation, and borrowing from abroad. His analysis is discursive rather than incisive. The book is a review of principles and problems rather than an analysis in depth pushing out frontiers of knowledge; it is pitched at a fairly high level of generalization and does not seek to provide an explicit set of prescriptions for the practitioner or the policy-maker. For example, in the chapter on inflation as a device for forcing saving, we are cautioned that inflation must be used discreetly, with restraint and for limited periods; in the chapter on taxation the author points to the need for reduced dependence upon indirect taxation, especially customs duties, and for improved tax administration; similarly, we are reminded that capital imports must be accompanied by an investment program sufficiently productive, properly timed, and balance-of-payments oriented, to facilitate debt service and repayment. But the author does not specify the degree of inflation, the tax structure, or the investment program to be followed. Presumably these things depend upon the particular circumstances of particular countries. These points are mentioned here (there are many others which might be included) only to illustrate that the author's purpose is to describe the sort of terrain through which an economy must travel and the general nature of the pitfalls to be encountered along the way; he does not give us a detailed roadmap of how to get from here to there. Given this limited goal, the book may be considered a successful effort.

The author has not completely freed himself of the limitations of analytical principles developed with reference to more mature economies. He has, on occasion, used Keynesian doctrines which are likely to have only limited applicability to underdeveloped economies. It is questionable, for example, that in an underdeveloped economy, the "social cost of investment projects" should be computed net of the increased income associated with the "induced multiplier effects" of the original increase in investment. Further, one may doubt that the experience of presently wealthy economies with respect to tax-paying capacity (as high as 30 per cent of national income) is a useful guide to the tax capacity of poorer nations.

Despite these quibbles, this little volume is a useful summary of existing professional thought on the problems and processes of financing economic development. The author's treatment is brief but it is also clear.

Ghosh leaves no doubt that he is favorably disposed toward the use of inflation (within certain limits and restraints) as one device to promote saving and investment. He includes a brief discussion of the cases of Mexico and Brazil (1945-52) to show that inflation may contribute to, or at least be consistent with, a high rate of capital formation and economic growth. Hasan's study of the Pakistan experience, however, raises anew the doubts about the general applicability of the Mexican and Brazilian examples.

Hasan's data show that Pakistan's money supply virtually doubled during the period 1951 to 1959. Roughly 85 per cent of this amount was attributable to government borrowing from the banking system, enough to finance 55 per cent of public development projects. Extensive debt monetization was accompanied by a chronic balance-of-payments deficit but only limited increases in aggregate capital formation and income. Paradoxically, the bulk of the growth of the period occurred during the first four years when the price level was actually falling because of a rising import surplus, (temporary) additions to hoards, and an overvalued currency. (Pakistan did not follow the Sterling Area devaluations of 1949 and there was a recession in Pakistan's export markets after 1952.) Following the devaluation of 1955, continued deficit financing was accompanied by dishoarding, and the price level rose 65 per cent by 1959; capital formation and growth, however, lagged behind population growth.

On the basis of these (and other) data, Hasan takes a rather dim view of inflation as a device to increase real investment and to accelerate growth. Nevertheless, one should not conclude that the experiment was an unmitigated failure. Real income did rise about 25 per cent during the period; the textile industry, expanding rapidly, acquired new capacity sufficient to meet all domestic requirements, and income from large-scale industry increased five-fold; current living standards improved substantially as indicated by rapidly rising per capita consumption of wage goods. A key fact—and lesson to be learned—is that the stagnation after 1955 was attributable primarily to an inability to capture or immobilize rising agricultural income. (In Pakistan, not unlike other poor countries, 60 per cent of the national income goes to the 80 per cent of the population in the agricultural sector; one-half of agriculture operates on a subsistence basis.)

At the risk of doing violence to Hasan's careful work we summarize the major conclusions to be drawn from his analysis as follows: (1) Despite a high rate of return on capital, in Pakistan as in most poor countries, private investment is not a sufficiently attractive alternative to consumption, hoarding, or capital export. This is true even in times of inflation. (2) Credit creation to finance public capital formation will, in the short-run, induce private saving and hoarding. Hoarding will be encouraged if, simultaneously, "superior goods" disappear from the market place (e.g., if importation of products important in the budgets of high-income groups is blocked by exchange control). (3) Eventually, as liquidity increases and money income rises, dishoarding, luxury consumption, and capital export increase the inflationary pressure on domestic resources and the balance of payments. (4) Most important of all, inflation in a predominantly agrarian economy means a chronic

improvement in the terms of trade of the agricultural sector vis à vis the rest of the economy and a reduction of agriculture's marketable surplus. Apparently the income effect of a price increase is large and negative—agriculture exhibits negatively sloping supply curves. This phenomenon, reinforced somewhat by rising consumer demand in urban areas, puts strong upward pressure on wage-good prices. In short, the Achilles heel of the inflationary device lies in the low propensity to save in the dominant agricultural sector and in the lack of a viable tax structure to absorb rising agricultural income. (This point is emphasized by Ghosh as well as Hasan.) In Pakistan, the inflation of 1955-59 was accompanied by an increase in real agricultural income, rising real per capita consumption, and a fall in the share of taxes in the national income.

Hasan makes imaginative and circumspect use of the limited available data and constructs an illuminating model of the Pakistan economy. His analysis is careful and concise. His case-study is one which students of inflation and the process of economic development should not neglect.

FRANK C. CHILD

Stanford University

Le trésor public et le mouvement général des fonds. By FRANÇOIS BLOCH-LAINÉ AND PIERRE DE VOGÜÉ. Paris: Presses Universitaires de France, 1960. Pp. 376. NF 20.

This is an authoritative treatise on one phase of financial engineering, the handling of public funds, including issuance, servicing, and redemption of public debt. The volume is centered on France, but its value is enhanced by comparisons with practice elsewhere. These comparisons are found throughout the volume; one of the most interesting is that presented in the concluding section, between the French tradition of frequent resort by the Treasury directly to the Central Bank, and utilization of the money market by the United Kingdom and U.S. Treasuries. In addition, the authors evaluate Treasury techniques in France in the light of broader objectives such as full employment and price stability; but these passages form only a minor part of the volume, and do not go deeply into the economic issues involved.

The introductory section supplies a concise and illuminating sketch of the historical development of the French Treasury over several centuries, with emphasis on the immense new tasks imposed on it by two World Wars, the depression, and the extension of state activity following the Second World War.

The succeeding sections in turn describe and analyze the Treasury in its role of manager of the public finances, its activities as a bank and part supervisor of the banking system and securities market, and its influence on the creation of money and the circulation of money among geographic areas and type of holder. It is in this last analysis that the authors present their comments on the Treasury and its techniques as one of several sets of mechanisms available for achievement of macroeconomic goals.

The French Treasury, partly owing to the philosophy of centralization characteristic of France since the Revolution and the Empire, and partly ow-

ing to the traditional isolation of the banking system from the long-term government securities market, came to carry a much larger share of responsibility for behavior of the money and capital markets than did its counterparts in the United States and the United Kingdom. A network of relationships peculiar to France has thus developed between the Treasury, the other financial institutions, and the money and securities markets. A precise understanding of this complex network is correspondingly helpful to one who wishes to comprehend the aims and effects of French fiscal and monetary policy.

Bloch-Lainé and de Vogüé have provided just this understanding. The description is lucid, replete with detail, yet so well organized and so well written that the reader is stimulated, not oppressed. This achievement is remarkable in view of the volume of technical information that must be transmitted to insure an understanding of the workings of the system.

The authors have not attempted to link their technical exposition closely with general treatments of fiscal or monetary policy in France or abroad; there is no bibliography, and there are no references to works other than French, and only to a few of those. But all this is perhaps largely explicable by the facts that the work addresses itself to the French scene, and that French public finance scholars, with a few recent exceptions, have not interested themselves or their students in the interrelations of the public finances and the money and capital markets. More questionable is the omission of sources for much of the tabular material. The lack of an index is partly offset by a detailed table of contents.

CARL S. SHOUP

Columbia University

Gegenwartsprobleme des öffentlichen Haushalts. Schriftenreihe der Hochschule Speyer, Vol. 12. Berlin: Duncker & Humblot, 1962. Pp. 183. DM 24.80.

This book presents a series of lectures and summaries of discussions on recent developments in the structure and classifications of budgets in various countries of the eastern European Continent. In the United States it has been recently intimated that the European countries in general present their budget data in an economically more meaningful manner.¹ The U.S. reader will therefore welcome a survey of recent budgetary developments in Europe. Indeed, there is much that he can learn from this volume.

However, the volume suffers from shortcomings which can often be found in proceedings of a conference. There are serious gaps in the countries covered. There is, strangely, no paper on France, which has adopted a most interesting budget reform in recent years (some reference to France is made in several papers of the volume). Also the treatment of the various countries is very uneven. Of special interest is a discussion of the budgets of the three organizations of the European Community. It is interesting to note that the sum total of the budgets of the six European member governments amount to \$37.5 billion, those of the three European communities to \$325 million.

¹In various official documents reference is made to an unpublished study by Andrew H. Cant II, Harvard University, comparing budget concepts of various European countries with those used by the United States government.

By far the largest space is devoted to the German budget problem. The German budget law was like that in the United States adopted soon after the end of the First World War and has been revised only piecemeal since then. The papers both by F. K. Vialon and P. Senf reflect the opinion that the German budget law is obsolete and does not do justice to the political, economic, and welfare functions of the budget. Vialon presents a criticism of the present budget structure and surveys a great variety of reform proposals, but it is difficult to find in his paper a clear and constructive program for budget reform (except that he suggests a freer hand for budget execution in accord with economic developments and he also asks for appointment of a commission for proposing a budget reform for the federal government and the *Länder*). Senf suggests a program classification of the budget and an interrelated national economic budget and government budget as instruments of an economic and fiscal policy.

What Senf proposes for Germany is, as he points out, largely accomplished in France. It has also been adopted in the Netherlands as J. P. de Loof explains in his two papers on the latter country. M. Frank's paper on Belgium reports on an attempt to provide by legislation for establishment of a fund for anticyclical budget policy. This attempt was a complete failure, and the author reaches the conclusion: "In other countries, measures were effectively adopted but not incorporated in a formal law. One should take to heart the experience that it is senseless to freeze economic and financial measures in formal laws." Of interest are the Swiss accounts of changes in government assets and liabilities as part of an integrated government accounting system. Also interesting is a description of the budget system of Yugoslavia with its decentralization of enterprises and autonomous organizations and local units. The following sentence is translated from the paper on Yugoslavia and not from a paper on a *laissez-faire* utopia:

State organs are not permitted in Yugoslavia to concern themselves with direct production. The State is also not permitted to offer nonmaterial goods or services. Beyond that: State organs also have no right to direct such activities directly or to determine guidelines for them. All work should be in the untied hands of the special organizations outside the government (enterprises, institutions, associations and so on).

GERHARD COLM

National Planning Association
Washington, D.C.

International Economics

Economic Aid to Underdeveloped Countries. By FREDERIC BENHAM. London: Oxford University Press for the Royal Institute of International Affairs, 1961. Pp. 121. \$2.00.

In the tradition of English scholarship, this compact book offers an illuminating overview of the international economic aid issue. Benham's lively writing style should satisfy the discriminating reader in that the unequivocal personal opinions expressed, based upon extensive travel and direct contact

with the problems of the "poor" world, have genuine policy overtones. Accordingly, this little volume will serve as a valuable supplementary text in a variety of courses dealing with the international economy.

The introductory chapter elaborates upon the distinction between the developed and underdeveloped countries, major differences among the latter, and provides numerous insights relating to controversies about economic growth. For example, Benham believes that conventional measuring techniques exaggerate global income differentials, and that generalized description (and prescription) concerning the underdeveloped countries is essentially useless, owing to widely diversified resource endowments. On the point of planning emphasis, he feels that a "balanced growth" program has much to offer, for "to concentrate on rapid establishment of manufactures is not in fact a short cut to prosperity" (p. 18). A widespread dearth of social services, including education and medical facilities, is recognized, but it is suggested that governmental outlays should be aimed toward more directly output-raising projects. Finally, he labels as "utter nonsense" Hirschman's (and Colin Clark's) view that population pressure leads to counterpressure or activity designed to maintain the level in a community, and makes a plea for an immediate international birth-control program (p. 23):

Unless the outstanding economic problem of limiting births is resolutely tackled, expenditure on palliatives in such a country [India] (whether from its own resources or from external aid) will largely be money down the drain.

Next, economic aid is defined in UN terms—i.e., assistance consisting only of outright grants and net long-term lending for nonmilitary purposes by governments and international organizations. Benham would accept this measure only if all public lending made on commercial terms were excluded. He is concerned with the granting of "aid" wherein debt service charges during subsequent years would impose a severe burden on the recipient country's balance of payments. The international flow of economic aid is then briefly examined as to source and destination; and it is noted that the contribution of France (mainly to her territories) has been greater in relation to her national income than in either the U.S. or the U.K. case. By drawing on the research of Alec Nove, it is duly recorded that the amount of Soviet aid has been exaggerated and that there is little likelihood the small volume will increase substantially in the foreseeable future.

Because the costs of needed capital assets are much the same throughout the underdeveloped world and real per-capita incomes differ widely, Rostow's "take-off" analysis is criticized as a policy guide on grounds that more is necessary than fixed "targets" of saving and investment. Discernible economic growth depends upon much more than a simple increase in capital formation—e.g., the character and abilities of the population, social customs, etc. In short, other things are in fact *not equal* when one contemplates an increase in investment outlays of a certain magnitude as a convenient vehicle to assure rapid economic development.

Chapter 3 deals with the problems of international trade in a rather con-

ventional terms-of-trade framework. The mechanics of commodity agreements and national stabilization measures are discussed in a fashion that outlines the formidable obstacles present in such arrangements. In response to the query as to what the industrial countries can do to aid in stabilizing the export earnings of primary producers, no very promising proposals are offered—e.g., they could lift import restrictions (without expecting reciprocity), artificially curtail domestic output of certain raw materials, grant easy loans to overcome balance-of-payment difficulties, and/or increase stockpiling operations of various commodities, etc. The political feasibility of implementing these “remedies” in any meaningful degree seems remote.

Chapter 4 is concerned with private capital flows as a source of needed funds. Owing to greater political stability, private investors prefer the more-developed countries, especially the oil-producing regions. As a result, “the poorest countries, with few natural resources and relatively small home markets, continue to receive little private capital” (p. 67). Other than foreign exchange losses from profit remittances, direct private investment activity does have advantages over high-interest loans to the underdeveloped countries in that new industries and technical training, etc., are provided. Nevertheless, rampant nationalism “. . . perhaps the greatest curse of our age, nearly always prevails” and serves to impede the flow from this source of help to many countries. In short, “there is nothing, say the Americans, so timid as a million dollars” (p. 80). Although some restrictions have been relaxed, private capital, at best, will only have a marginal impact in the battle to overcome poverty even though greater reliance upon the role of private enterprise is urged as a general goal of development policy.

Finally, Benham evaluates the motives for granting aid and asserts (naively?) that moral duty should provide the primary impetus, albeit the political-military rationale of “holding the line” in the cold war is recognized and subsequently questioned. In the first place, what is often labeled Communism embraces a wide range of the ideological spectrum. Secondly, “it is not true that poverty breeds Communism” (p. 89)—the discontent generated by hasty industrialization efforts provides fertile soil for propaganda seeds. With reference to the arguments against continuance of economic aid, let alone its expansion, the politically untenable proposals (involving a 75-year “intellectual lag”) espoused by M. Friedman and P. T. Bauer suggesting that more harm than good is done by such misguided generosity are patently denied. In fact, some students honestly feel that a degree of *central planning* is necessary, while the building of alleged “modern monuments” (e.g., steel mills) in certain countries is highly desirable, classical trade theory notwithstanding. Concerning future aid allocations, however, many will reject Benham’s notion that “. . . surely the interests of the underdeveloped countries should come first” (p. 103) and that grants—with a single “string” that insures the maintenance of basic human rights—are preferred to burdensome loans. Also, it appears to be unrealistic to plead for greater multilateral aid—ostensibly via the United Nations—while continuing present bilateral arrangements.

Although the U.S. public might legitimately reject certain of the author’s

value judgments, he does offer a provocative review of the aid issue. Indeed, it is unfortunate that the book was not expanded in order to allow a more extended discussion. Too, in view of the concise nature of the argument, a bibliography would have been a useful supplement to guide the ambitious reader.

J. D. DeFOREST

Denison University

The Problem of International Economic Equilibrium. By FRIEDRICH A. LUTZ. Amsterdam: North-Holland Publishing Co., 1962. Pp. 75. Paper, \$1.85.

This slim volume contains the text of three lectures delivered in the Netherlands at the invitation of the Professor F. de Vries Foundation. It deals with the major causes of international disequilibrium, considers various types of remedies, and concludes with a discussion of the problem of international liquidity.

Lutz believes that three factors have been primarily responsible for the balance-of-payments difficulties after the Second World War. First, there is the monetary factor of different rates of inflation in different countries. Secondly, on the real side, unequal rates of productivity growth per unit of labor have also contributed to disequilibrium. And finally, there is the factor of long-term capital movements. A two-country model is employed in the analysis of all three cases.

Since trade restrictions and exchange control are obviously undesirable, the author rules them out as solutions. Objections are also voiced against arrangements which require surplus countries to extend credit or donate to deficit countries. These would not only force capital movements in an arbitrary direction without regard to the criterion of relative profitability, but also tend to encourage countries to run a deficit and penalize countries achieving a surplus. At best, they only treat the symptoms rather than the disease.

To strike at the root of the malady, it is necessary to adjust the relative cost or money-income levels either directly, or indirectly through alterations of exchange rates. The effective adjustment of cost levels, however, requires a degree of flexibility which is lacking under modern conditions. As to income levels, since expansionary adjustments are easier to make than contractive ones, the danger is that surplus countries will be pressured into bearing the chief burden of adjustment, with excessive expansion and world inflation as the likely result. Thus to Lutz the best answer seems to lie in the only other alternative, namely, a system of flexible exchange rates.

In the last part, the author offers his thoughts on the problem of possible future deficiency of international liquidity. The proposal to raise the price of gold is dismissed as impractical because the move is apt to impair confidence and create inflation which would then quickly absorb the newly augmented money value of international reserves. Neither is Lutz enthusiastic about the Triffin Plan which, roughly speaking, would convert the International Monetary Fund into a sort of World Central Bank. The Plan contains certain features of compulsion, and at any rate it is believed to be no better than a sim-

pler system wherein several key currencies would serve as reserves along with gold.

On the whole, this book represents a useful if overly condensed package of analytical material. But two criticisms may be in order. First, analytically, the author is in the habit of assuming that an equilibrium price is always arrived at instantaneously. In arguing against the purchasing power parity theory, for example, he states that in view of the law of one price in the world market, the price index of international goods cannot change in one country without a simultaneous proportionate change in the other, and it is thus meaningless to base the exchange rate on a comparison of such indices. Again, in connection with different rates of inflation, he reasons that an inflation in one country will immediately push up the "world price," i.e., raise the price level in the noninflation country to an equal extent. This time, however, instead of helping the argument, the assumption of instantaneousness merely deprives him of the use of price differentials as an explanatory factor in the resultant disequilibrium.

The second criticism has to do with policy prescription. Most curiously, after pointing out the desirability of flexible exchange rates, the author proceeds immediately to tell his reader that the actual adoption of this solution is very unlikely, simply because flexible rates are formally excluded by the statutes of the IMF! This is indeed like telling a hungry youngster that there is a nice piece of pie in the refrigerator, but since the door is closed, he had better give up the idea of eating. If flexible rates are truly better as alleged, why could not the statutes be amended? On the other hand, if there are good reasons for not changing the statutes, why should the author advocate flexible exchange rates in the first place? The reader is left to wonder.

ALPHA C. CHIANG

Denison University

Canada in a Changing World Economy. By HARRY G. JOHNSON. Toronto: University of Toronto Press, 1962. Pp. 62. Cdn. \$2.50.

In two Alan B. Plaunt Memorial Lectures delivered at Carleton University, Ottawa in February 1962, Professor Johnson informed his fellow Canadians of the failings of their recent economic policy with his customary forthrightness. The book contains illuminating and stimulating remarks on a great number of subjects, but only its outline can be drawn in a review. The first part describes contemporary changes in the world economy; the second part discusses Canada's position, her policies and what they might be in future.

To Johnson the fundamental change taking place in the world economy is the relative decline of North America caused by the rise of effective competition in manufacturing in Europe and Japan and by the spread of industrial production to other areas. The formation of the European Economic Community is a manifestation of the increasing power of Europe. The United States fostered European cooperation by its postwar policies and is now handicapped in stemming the movement to regional economic blocs by the weakness of her balance of payments caused by an inadequate international monetary system.

Turning to the Canadian situation, Johnson notes two problems: that of combatting economic stagnation and that of developing a trade policy adapted to new international arrangements. The first, vastly more important, is a "problem whose solution is fully within the competence of the Canadian government" (p. 33). By this Johnson means that an increase in demand would reduce unemployment, not that a simple cure for inadequate growth exists. In two brilliant pages he describes how unduly restrictive monetary policy in a country with a floating rate of exchange has manifestations which give rise to plausible, but fallacious, explanations for the depression. Because high rates of interest induce an inflow of capital and a high rate of exchange, inadequate demand for domestic output is blamed on foreign investment or foreign competition. The uneven incidence of a decline in demand leads to claims of structural maladjustments, and the earlier firing of less-skilled than more-skilled workers gives rise to claims that the cause of unemployment is an inadequately trained labor force.

It appears to this reviewer that past errors in Canadian monetary policy are the sole (and insufficient) justification for the abandonment of the floating rate of exchange for a fixed rate in June 1962. This will force Canada to maintain monetary conditions little different from those in the United States. But such a tie is desirable only if foreign monetary measures, taken as they are to affect foreign economic conditions, are more appropriate to Canadian conditions than the measures an unfettered Canadian monetary authority would take autonomously.

Johnson is less certain both of the goal and of the means of achieving it when he goes on to discuss growth in productivity. His chief recommendation is that the government should offset the retarding effect on growth of the size of its own operations, and of the consequent taxation, by budget surpluses to increase savings and low rates of interest to stimulate investment.

Turning to trade policy, Johnson calculates that the potential loss to Canada from European developments is less than generally believed and criticizes the Canadian government's "vain . . . and undignified effort to deter the British from seeking or gaining membership in the Common Market . . ." (p. 50). Of the policies Canada might attempt, Johnson believes that association with the Common Market is impossible of achievement, because of the European political purpose of EEC, and is in any event undesirable; and that a North Atlantic free-trade area is also impossible, because the United States would not discriminate against third countries. The formation of a customs union between Canada and the United States would bring economic gains, but the opportunity for its formation does not exist owing to the present U.S. desire to promote multilateralism. Canadian policy should support the present initiative of the United States in lowering tariffs so that Canada might obtain the benefits of greater specialization by exports and more efficient market structure for domestic industries.

In these lectures for a general audience, Johnson dramatizes the view that support of the present U.S. policy would represent a departure from the traditional Canadian policy of promoting trade with Europe, as a defense against

the United States, and of protecting domestic manufacturing industry. However, cooperation with the United States in liberalizing trade on a multilateral basis would also be following tradition and would be a revival of the leadership these countries gave in the early days of GATT before the present stagnation made men fearful.

Modern International Economics—A Balance of Payments Approach. By MAX J. WASSERMAN AND CHARLES W. HULTMAN. New York: Simmons-Boardman, 1962. Pp. x, 494. \$7.75.

It has been said that books constitute the greatest teaching machines ever invented. This volume is clearly a textbook whose pretensions to originality are limited to pedagogy. Whether it will prove to be a good teaching machine will depend upon what the teacher hopes to accomplish and his own skill in supplementing the book where it may fall short of course specifications. Its claims to pedagogical distinctiveness are that it is a "balance of payments approach," describes a *real* world, and treats theories and policies that are important and relevant *today*. This is another way of saying that the historical and theoretical aspects of the subject are minimal, emphasis is placed on contemporary problems, and description is included at the expense of analysis. Nevertheless, within the limits of its mission, the book is complete and well written. It should prove most useful to readers whose interest and background in economic theory are sketchy.

Though the jacket and the title page carry the subtitle "A Balance of Payments Approach," a careful reading will show this to be somewhat of a misnomer. There is included more than the usual formal and detailed description of the international accounts, but the balance of payments by no means serves as a unifying theme for the whole book. For example, Chapter 5, "Balance of Payments: Analysis of Surpluses and Deficits," treats gold and short-term asset and liability movements in accounting terms, not in terms of price disequilibrium or internal or external imbalance (though here, as in numerous other instances, the terms are introduced but an explanation of their significance is left to the instructor, or the reader's use of the bibliography). Then in Chapter 7, "Financing International Transactions: Monetary Systems," gold and foreign exchange standards are described, likewise without significant reference to the theory of equilibrium, but also with only the most superficial reference to the balance-of-payments analysis of Chapter 5. The treatment of the rate of exchange is simple and clear but makes almost no reference to the earlier balance-of-payments analysis.

The book is divided into seven parts and 26 chapters. The two chapters in Part I are introductory. The four chapters in Part II present a comprehensive description of the balance of payments. Part III on international payments on the whole is well done, though the reader is presumed to have had prior knowledge of financial instruments. The treatment and comparison of the Sterling Area and the Franc Zone in Chapter 10 are especially good. Part IV includes four chapters on "The Movement of Goods, Services, Uni-

lateral Transfers, and Capital" in which the terminology is that of the balance of payments but the method is traditionally descriptive, and basically not payments-oriented. Part V presents in two chapters "The Theory and Analysis of International Economics," almost as if theory is discrete and separable from the rest of the subject, and can be disposed of in a small but neat package. Part VI, "Foreign Economic Policies," is a series of six chapters primarily devoted to a descriptive inventory of policies and an analysis of their effects. In this section the authors disagree with the position that trade substitutes for factor movements tending thereby toward factor-price equalization, and no mention is made of the role of education in bringing various national labor forces toward parity as productive factors. In Chapter 21, partial equilibrium analysis is applied to the effects of trade restrictions, but the results are spotty since this method of analysis is not used uniformly throughout the chapter. Part VII, "International Economic Development and Cooperation," presents a good summary of the methods and obstacles to economic development, though again no reference is made to balance-of-payments analysis. The last three chapters on international agencies are comprehensive and useful.

Each chapter is followed by a list of questions suitable for short papers or to evoke discussion. Of considerable interest are the analytical bibliographies for most of the chapters. A brief description of the author's position or the coverage of the book is given for a wide variety of sources. Whether the space for this purpose is well used depends on whether students will be prompted to read more widely than their assignments require.

The book has manifest strengths which merit its careful consideration for courses in international trade whose orientation is toward description and policy.

SAMUEL E. BRADEN

Indiana University

Business Finance; Investment and Security Markets; Insurance

The Investment, Financing and Valuation of the Corporation. By MYRON J. GORDON. Homewood, Ill.: Richard D. Irwin, 1962. Pp. xiv, 256. \$6.50.

The book is concerned primarily with the development of a theory of stock pricing and the empirical testing of this theory with the ultimate objective of using the theory to determine those investment and financing policies which maximize the value of the firm's stock. Much of this material has been published by Gordon in various journal articles, but there is considerable that is new, and the book has the advantage of considering many interrelated problems in more detail than is possible in journal articles, and analyzing them all within a consistent framework. While the analysis is not always completely convincing, it is the best comprehensive discussion of these problems which this reviewer has seen.

Slightly more than half of the book is devoted to a presentation of Gordon's theoretical apparatus, including a discussion of the theoretical literature. The

remainder is devoted to a presentation of his empirical results and their implications for investment and financing decisions. Unfortunately there is no discussion of empirical work done by others.

The theory of stock pricing is based on the assumption that the value of a stock is the present value of the future dividends which will be declared on that stock. Gordon then considers, pretty much independently, the determination of the future dividend and the determination of the discount rate. The dividend stream depends upon the fraction of earnings paid out in dividends, the rate of earnings on new investment, the funds obtained from outside debt-financing as measured by the debt-equity ratio, and the funds obtained from outside equity-financing. In his empirical work, Gordon assumes that the dividend pay-out rate, the earnings rate, and the debt-equity ratio do not vary from year to year in the future, and that new equity-financing is the same proportion of book value each year. He discusses the theoretical possibility that the earnings rate on new investment depends upon the amount of investment, but this does not enter into the empirical work. He investigates empirically a model which ignores debt-financing and a model which considers debt-financing, and finds that the model with debt-financing fits the data better. The same procedure suggests that the inclusion of outside equity-financing is not worth while.

The discount rate depends upon the risk associated with the dividend stream, and risk depends upon the rate of growth of the dividend, corporate size, the variability of earnings, debt leverage, the liquidity of assets, the maturity structure of the debt, and the outside equity-financing rate. The last risk factor is dropped because outside equity-financing adds nothing to the empirical properties of the model, and the debt-maturity factor is dropped because it does not improve the fit of the model to the data. The other risk variables are found to be empirically significant. A risk factor for leverage which takes advantage of the Modigliani-Miller theorem¹ gives a better fit than one which does not take advantage of this theorem.

The empirical results are then used to test the sensitivity of share price to changes in the other variables, and to show how the firm can select its dividend pay-out rate and its debt-equity ratio so that the share price will be maximized. These are the only two variables in the model which can be determined by the firm, and they jointly determine the amount of investment which the firm will undertake, and the way in which this investment is financed. Gordon also shows how the firm could use this model to make its investment and financing decisions if it could determine the relationship between the rate of return on investment and the amount of investment.

The great strength of this book is that it presents a thoughtful discussion of virtually all of the factors which are important in stock valuation or investment decisions, and that it combines theoretical analysis with empirical testing of the models. It should prove useful to all students of these problems. Its principal weakness is that too much theoretical importance is attached to assumptions which are made for empirical purposes. For example, Gordon as-

¹ Franco Modigliani and M. H. Miller, "The Cost of Capital, Corporate Finance and the Theory of Investment," *Am. Econ. Rev.*, June 1958, 48, 261-97.

sumes that the firm's dividend pay-out ratio will remain unchanged forever. This assumption is made because the model requires that the dividend be predicted forever, and this seems to be the most reasonable assumption about future pay-out rates. It also works quite well empirically. It does not follow, however, that a firm which bases its investment decisions on this assumption will thereby maximize the value of its shares. This criticism, however, means only that while Gordon's work is important, there is still more to be done.

Business Organization; Managerial Economics; Marketing; Accounting

The Role of Anticipations and Plans in Economic Behavior and Their Use in Economic Analysis and Forecasting. By FRANCO MODIGLIANI AND KALMAN J. COHEN. Urbana: University of Illinois, 1961. Pp. 166. \$2.75.

This theoretical work offers a number of fruitful insights into the role and uses of anticipatory data in economics. It also should stimulate empirical research in "semicausal" forecasting—the authors' term for attempts to integrate anticipatory data and "causal" variables in prediction. It is therefore a valuable book, as might have been expected from the authors. My chief criticism is that the analysis is very formal and frequently too detached from empirical issues. Some of the theoretical findings seem to point toward lines of research that should be pursued in collecting and analyzing anticipations data. But the authors fail to use many of these opportunities to point the way for empirical research. Also, the analysis could have been enriched and clarified by more use of empirical examples from the literature (including some of Modigliani's findings).

Part I explores the role of anticipations and plans in entrepreneurial decision-making. In the Modigliani-Cohen analysis, the firm is concerned about the future insofar as any forthcoming development bears on its choice of decisions in the present. Any aspect of the future that would not influence the firm's current actions is irrelevant and can be ignored. Modigliani and Cohen discuss in detail the conditions under which future parameters are relevant or irrelevant, thereby indicating where a firm is likely to concentrate its efforts at forecasting and how far into the future the firm is likely to look ahead.

However, the analysis runs into a major paradox. The firm need never explicitly know what it is going to do tomorrow in order to make the best decisions today. It needs considerable information about the environment of tomorrow and beyond, but it can optimize its current actions without specific reference to its own proposed future behavior. As the authors clearly recognize, in their theoretical framework there is no point to planning!

Why firms do plan is treated briefly. Two reasons are offered: first, in many cases, an indication of probable optimal decisions for the future emerges from the process of making a current decision with no—or little—added cost. Even though the decision for future action is subject to change, the firm might as well grind out a tentative decision in formulating its current policies. Plan-

ning ahead then economizes on the frequency and costliness of decision-making. The other reason, the authors suggest, lies in the "coordinating function of the plan"—its use in transmitting to the various parts of an organization information which is relevant to their present actions. Planning is a method of calling signals to the members of a team.

These are interesting and stimulating observations, but they lie outside the algebraic core of the book. With additional work following these insights, the authors might have developed a theoretical formulation in which planning did emerge as a constructive economic activity. I believe that such a course would have brought them into a closer inspection of empirical knowledge concerning what actions firms do plan and how, in fact, they make use of their plans.

Part II discusses the uses that economists can make of anticipatory data. Its chief contribution lies in clarifying the relationship of anticipatory data and other economic variables in forecasting. The central analytical concept is the "realization function" which relates the difference between actual and planned actions to unforeseen developments in the environment. Planned actions are based on expectations about the state of the world. Actions diverge from plans because the expectations sometimes turn out to be incorrect. The actions for a given period are then determinate if one knows: (1) the planned actions, as recorded at a previous time; (2) the expectations about relevant variables outside the control of the firm for the interval between the time of planning and the time of action; (3) the actual course of these variables; and (4) the way the firm responds to surprises in these variables.

This list introduces traditional causal factors, along with plans and expectations, as necessary tools for forecasting. If surprises in orders, prices, or costs can lead to revisions in plans for capital outlays, then the forecaster must judge how the firm is likely to be surprised and how it will behave in light of such surprises. Thus Modigliani and Cohen establish the logical foundations for the principle that causal and anticipatory data are complementary inputs in forecasting.

One empirical issue that deserves exploration lies close to this analysis. Bias and other systematic patterns of error are apparent in certain intentions series (e.g., Commerce's recently-launched inventory survey). According to the Modigliani-Cohen framework, actions will diverge from plans only if firms are surprised. Systematic divergences should appear only if firms are biased forecasters of the variables outside their control, or if they respond asymmetrically to surprises in opposite directions. It would be interesting to examine the systematic errors in light of this analysis.

Analytical uses of anticipations data get equal weight with forecasting uses in the title of this book. But they get omitted from most of the text. The two passages (pp. 128-29, 151-52) in which analytical uses are discussed cannot do justice to the potential importance of this area or to the work of other investigators. Knowledge of the course of expectations and how they are formed can potentially contribute much to our understanding of economic behavior. It might teach us how to weigh the now imponderable factors of "confidence" and "business psychology" and to appraise their roles

as determinants of economic decisions. It might help to appraise the dynamics of responses to changes in economic conditions.

Since the authors have so little to say on these issues, they might well have dropped "Economic Analysis and" out of their 17-word title. Perhaps they may turn their attention to the analytical uses (and to some of the empirical issues) in future work.

ARTHUR M. OKUN

Yale University

An Inquiry into Some Models of Inventory Systems. By MARK ALFANDARY-ALEXANDER. Pittsburgh: University of Pittsburgh Press, 1962. Pp. vii, 108. \$7.00; paper, \$4.00.

There is now a large literature dealing with the theory of inventory management. Although the subject bristles with difficulties, some outstanding work has appeared. As Dorfman has remarked, however, inventory theory consists of a battery of techniques adapted to specific circumstances rather than a simple, generally applicable body of doctrine.¹

The brief volume reviewed here attacks the subject with the aid of simulation techniques. After a short summary of some characteristics of earlier work and methodological matters, the author proceeds to an investigation of four inventory policies. These were chosen on the grounds that they are commonly used in industry, that they are simple rules that have been proven optimal policies under many realistic sets of circumstances, and that some of their characteristics appear to be in question (p. 11). No information is presented regarding the relative frequency with which the various models or variants thereof are in use in industry.

The study concentrates on the commodity inventory problem under conditions of uncertainty independent of the production process. Demand and price are taken to be beyond the firm's control, and speculative demand for inventories is ignored. Demand in each period and delivery lag time are both assumed to be stochastic variables. Demand in each period represents a random drawing from an exponential distribution, delivery time from a normal distribution. The four policies include: a "multibin" policy (multibin rather than two-bin since orders may occur when earlier orders are still outstanding) with a fixed order size triggered when existing and previously ordered inventory is equal to or less than a reorder point, s ; an " (s, S) " policy with a variable order size equal to the discrepancy between the inventory and the level of replenished stock, S , also initiated by a decline in inventory to the reorder level, s ; a "base-stock" policy which is simply an (s, S) policy with $s = S = B$, where B is the base stock; and a "fixed-order cyclic" policy with a periodic ordering rule having no feedback adjustment. The models take account of holding cost, requisition cost, and shortage cost. With respect to the last, each model has two variants. In the one case, demand in excess of stock on hand is lost forever (impatient customers); in the other, any shortage is backlogged (patient customers). The author uses a "rationalized cost coefficient" in an effort to make his results as general as possible.

¹ R. Dorfman, "Operations Research," *Am. Econ. Rev.*, Sept. 1960, 50, 590.

The purpose of the study is twofold: to investigate the long-term expected costs for each model given various values of the parameters (such as costs) and decision variables (such as reorder point and order size), and to suggest an heuristic model for inventory decisions useful to actual firms. The former entailed computer simulation of many-period results (usually around 500 periods) for various combinations of values of the parameters and decision variables, and subsequent analysis of response surfaces to estimate optimal values of the decision variables. A comparison of the optimal results for the four policies indicates little basis for choosing among the first three, given the assumptions employed. The last is a distinctly higher-cost inventory system. A graphical portrayal of results occupies 35 pages of appendix.

The exposition could be improved substantially; e.g., no reference is made to the fact that the distribution function discussed on page 61 is a cumulative distribution function. Similar difficulties appear elsewhere. Though little use is made of mathematics, the development presupposes familiarity with the vocabulary and methods of inventory theory (and, on occasion, electric circuit theory). But these should not be barriers to most of those likely to make use of the study.

A work like this contains little of interest to economists not concerned with detailed analysis of the firm. This is not to say that economists should not have some minimum acquaintance with inventory theory and its problems.² Nor should this remark be interpreted as a criticism of work specifically oriented toward industrial management.

H. LAURENCE MILLER, JR.

University of California, Los Angeles

² As discussed, e.g., in the first two chapters of the recent book by K. J. Arrow, S. Karlin, and H. Scarf (*Studies in the Mathematical Theory of Inventory and Production*, Stanford 1958). This particular discussion has the virtue of simultaneously introducing the reader to the nature of inventory problems in general and to the close tie between this subject and the demand for money.

Industrial Organization; Government and Business; Industry Studies

Organization, Automation, and Society—The Scientific Revolution in Industry. By ROBERT A. BRADY. Berkeley: University of California Press, 1961. Pp. xiv, 481. \$8.50.

Thirty years ago, Professor Brady described the rationalization movement in German industry as a search for "ways and means of systematically introducing standardization, utilizing the fruits of cooperative research, promoting scientific management, and coordinating and integrating activities of entire industries" [2, p. xii]. Rationalization, Brady emphasized, was a revolutionary phenomenon. "Under its complete domination nothing would be left to chance, for it substitutes conscious control for automaticity, ordered discipline for caprice, systematically articulated plans for chance coordination. It represents the bold attempt to bring all phases of economically significant human activity under the direct management of the human agent" [2, p. 416]. *Durchrationalisierung* (permeation of rationalization) of all eco-

conomic activity and *Verwissenschaftlichung* (scientification) of all techniques and methods, wrote Brady, would transform economic organization under the aegis of "plan, order, system, foresight, control and rational guidance" [2, p. viii]. In essence, said Brady, *rationalization is planning*—and though the German movement was never able to match promise with fulfillment, it at least moved in the right direction.

Today, Brady is still fascinated by the character and implications of the scientific-technological revolution—what Veblen called "this concatenation of processes" under the impact of which "the modern industrial system at large bears the character of a comprehensive, balanced mechanical process" [5, p. 16]. In *Organization, Automation, and Society*, Brady attempts to comprehend this revolution and to address himself to what he regards as the dominant question of our time, viz., whether production can genuinely be "scientifically organized" [3, p. 387]. It is the best study of automation yet to be made. It is the scholarly, sensitive, and insightful product of a brilliant and imaginative intellect.

The new scientific-technological revolution—which differs as radically from its 18th century antecedent as the latter did from the handicraft era of the middle ages—has four general and interrelated aspects:

First is the chemical revolution in the materials foundation of industry. Second is the standards and specifications revolution in the criteria for selecting the best methods, processes, products, and the like. Third is the electronic and automation revolution in the processing methods of industry. And fourth is the revolution (at the moment, primarily atomic) in the systems of energy supply [3, p. 5].

The new mass production which Brady envisions as the outgrowth of this scientific-technological revolution has the following characteristics: (1) plants are automatic or near-automatic; (2) plant-agglutination and plant-scattering patterns are determined without respect to property lines or corporate divisions of ownership; (3) interplant flows are modeled upon the pattern of intraplant flows; (4) capacity and load factors approach the 100 per cent limit ("the never-quite-attainable ideal being production to rated capacity around the clock and 365 days in the year" [3, p. 399]); (5) all articles and their components are designed in accordance with rigorously formulated standards and specifications, drawn in keeping with physical-chemical characteristics and functional usefulness; and (6) all or nearly all costs—investment and operating alike—tend cumulatively to take on the character of overhead costs [3, p. 231].

To achieve this automated industrial system, the operation of related plants must be revised "*as though* the entire concert of such plants were (a) converted to an automation basis and then (b) proportioned in size, scheduled in production, and synchronized on a quasi-automatic basis" [3, p. 265]. Volume and timing between successive steps must be dovetailed; storage and inventory at any given point must be held to a minimum; materials flows and manufacturing schedules must be synchronized by automatic or quasi-automatic feed-back controls. In short, each specialized plant in the economy must be conceived "*as though* it were a single functioning unit re-

lated to the rest in somewhat the same way as the separate parts-producing units within the plant are interdependent at the assembly line" [3, p. 266].

The inner logic of the new order, says Brady, extends beyond the industrial sector. Under its imperatives, mining must be reorganized and "unitized" like gas and oil extraction, so that each deposit is exploited as a single production unit [3, pp. 145-57]. Rail, water, highway, and air transportation must be integrated as coordinate parts of a regional or national traffic system [3, pp. 267-95]. Power generation, transmission, and distribution must be unified on the widest possible regional and interregional basis (along TVA and Central Valley Project lines) with a coordinated utilization of an extraordinarily wide range of natural resources [3, pp. 296-325]. Telecommunication networks, wireless and wire alike, must be integrated in operation and equipment manufacture [3, pp. 361-86]. Scientific research must be reorganized, so that our present "pell-mell" effort in this field is replaced by national mobilization of resources and long-range planning.

Not only must a greater proportion of our research effort be devoted to fundamental or basic research, but the whole effort must be better organized and administered [3, pp. 72-107]. In agriculture—to illustrate the kind of "rethinking through" which Brady advocates—

. . . plans for production would differentiate land use in terms of basic meteorological and hydrological cycles, soil types, and topographic features; would adjust crop patterns and fertilization to maintain old or establish new ecological and soil-chemical balances; would consider farming as merely one of several multiple-purpose uses of water resources to be cooperatively developed within river valley profiles as a whole; would specialize land in crops within and among major producing areas in terms of the product mix demanded by society at large; would plan a size and scale of farm operations which approaches, with full mechanization and within the limits set by the agronomic sciences, the conditions of optimal economy in production [3, pp. 398-99].

In this kind of industrial society, obviously, the physical unit of reckoning is typically large and the time span of planning is long. In the extractive industries, the minimum unit is not the mine, but the deposit. In agriculture, it is not the family-sized farm, but the combination of meteorological, hydrological, topographical, and soil-type patterns. In water resources, it is not the single power-generating facility but an entire river profile system. In mass production, it is not the individual plant, but an industry fully integrated—forward and backward. Throughout, the pressures are multiplying to consider the minimum-sized unit for actual day-by-day management and operation as a mere operational unit in a larger frame of reference.

More clearly than in any previous rationalization movement,

. . . current plans for industrial reorganization are coming to focus on problems of size, proportioning, and process or product specialization of all plants in each industry; of location of these plants and their supplies with a view to elimination of cross-hauling; of specialization of traffic movements by most economical transport or combination of transport media; of industry-wide pooling of research, technical know-how,

and management information about products, markets, costs, and prices; of common promotion, development, and widening use of standards, grades, and specifications [3, p. 405].

In short, the sweep of the scientific-technical revolution is rapidly transcending the current framework in which problems of industrial organization and public policy are being discussed.

In the technocratic society envisioned by Brady, the conflict between freedom and order assumes new dimensions and crucial significance. The new technology requires facilities, simplification of procedures, organization and integration—"order"—on an unprecedented scale. The main thrust is to avoid anarchy through planning. At the same time, however, this goal may have to be purchased at a considerable price. To obtain "order" and to avoid "anarchy" is to face "the possibility, however remote, of authoritative direction and the erosion of individual initiative" [3, p. 390]. At its very best, the degree of centralization implicit in the new order may mean massive bureaucratization, internecine warfare between monopolistic power blocs, and excessive political interference. At its worst, it may lead to the perversion of science and technology toward the ends of war and the destruction of human life itself.

Even two decades ago, in discussing the comparative virtues of capitalism and socialism, Oskar Lange shrewdly recognized that the real danger of socialism was "not the impossibility of coping with the problem of allocation of resources," but rather the "*bureaucratization of economic life*" [4, p. 109]. This Weberian curse (from which capitalist societies are by no means immune) involves the risk of economic conservatism and entrepreneurial atrophy—the danger that the managerial class may not probe for better ways unless forced to do so by powers beyond its control. The bureaucratic mentality, as I have observed elsewhere [1, pp. 269, 274], tends to infest the socialist planner as well as the private monopolist. It transcends national boundaries and defies ideology. It is hostile to novelty. It is rigid. It is anti-experimental. It is addicted to the status quo. It is activated not so much by a desire for monopoly profits as for the quiet life. It seeks to insulate itself from the winds of change. Imagination, daring, and initiative are outside its lexicon of virtues. Its slogan is to let well enough alone.

Here is the nub of the problem. If Lange is right, if bureaucracy is indeed the great danger, then the goal of public policy must be to curtail this mortmain and *Kadavergehorsam* rather than to sanctify it with official anointment. The goal must be decentralization of authority, dispersion of the centers of initiative, autonomy for the seedlings of initiative. The objective must be to give the "market" greater play, because the greatest threat to encrusted bureaucracy is the challenge of "competition" (governmental or private), the existence of a yardstick by which to measure performance, the presence of alternatives to centralized decision-making. "Competition" (in the sense of exogenous control forces) is what the bureaucrat fears most, because it compels him to submit to the "public will." It enables him to survive and prosper only by being the public's servant, and not its master.

Brady, of course, is too sophisticated a scholar to ignore these problems of the brave new technocracy. He is fully aware of the Orwellian dangers in-

herent in the scientific-technological society. "Bureaucracy," he wrote long ago,

is coterminous with settled, patterned, ritualized behavior. It does not arise from ill will, but from behavior which has become routinized and frozen to its mold. As found in industry and commerce, bureaucracy represents the dead hand of the past. . . . It represents human inertia coupled with custom and taboo and frozen into a routine of perfunctory performance of formal duties. It is to be found in all human behavior; it becomes more marked, more noticeable, more decisive, and more dangerous the older and the more complex the institutional setting in which it is found [2, pp. 40-41].

In his latest book, Brady elaborates this insight, recognizing that massive bureaucratization may well nullify the enormous productive potential of which the newly emerging industrial order seems capable. Bureaucratization in large-scale organizations, he says, reflects "the laudable desire to divide, specialize, train, regularize (i.e., subject to rational, impartial rules), and coordinate duties, functions, and responsibilities" [3, p. 415]. On the other hand, it threatens to strangulate economic activity, like the serpents entwining Laocöon. Inevitably expanding with the growth of giant economic organisms, bureaucracy has become a force, especially in countries like the Soviet Union, which increases in strength and ingenuity with every effort to cut through its endless coils and Parkinsonian complexity. It threatens to become a dead weight on modern industrialism—much like the courtly retinues of a bygone age which attended the whims of the wastrel nobility while almost eating them out of house and home.

Thus, Brady would be the first to admit that the rational organization and productive potential, made possible by the inner logic of the new industrial revolution, may well be frustrated by pervasive bureaucratization. He recognizes that, at all levels, the challenge is to "combine coordination with individual initiative, organization with autonomy, effective interlacing of independent activities with flexibility and the need for change" [3, p. x]. In fact, he indicates that *Organization, Automation, and Society* was to be but the first volume of a trilogy—to be followed by a study of "bureaucracy, considered as the 'problem of flexible organization,' as it might be designed to manage the type of emerging industrial order outlined here" and by a final study of "the types of policy which might (1) make most rational use of the new industrial apparatus, while (2) surmounting the dangers of bureaucratic arteriosclerosis, and (3) yet be most consistent with both democratic institutions and the values of individual personality" [3, p. 428 n.].

Would that Brady, or someone of his stature, intellect, and sensitivity, might devote himself to this unfinished task.

The Economics of the Electrical Machinery Industry. By JULES BACKMAN. New York: New York University Press, 1962. Pp. xxiii, 374. \$10.00.

The Gentlemen Conspirators: The Story of the Price-Fixers in the Electrical Industry. By JOHN G. FULLER. New York: Grove Press, 1962. Pp. 224. \$3.95.

John Maynard Keynes, in a book of 384 pages, dismissed the "classical" economists in 18 lines, but at least took 19 more pages to explain himself. Professor Backman, in a volume of 374 pages, has dismissed the great price-fixing cases of 1960 with 3 pages (pp. 135-38). Neither the "classicists" nor the cases should be treated so cavalierly.

There is, however, much of value in this "industry study." The 323 pages of text contain 39 text tables and 22 charts. In the appendices are 32 additional tables, more detailed and basic than those of the text. One finds no less than 600 footnotes, many containing multiple references. The work was obviously a formidable task of research, writing, and editing, and Backman was fortunate in apparently having the substantial aid of his staff and others: Schwartzman of the New School, Blum of Michigan State, Gomez, Guilfoil, and Levine of New York University.

This study of the electrical machinery industry makes use of most of the concepts and raises most of the questions appropriate to an industry study: the size and significance of the industry in the total economy, growth and financing of the firms, the structure of the industry, the nature of competition, the "performance" of the firms judged by the usual criteria (but not much on "behavior"), pricing policies and practices, productivity, profit rates, and wage patterns. There are two chapters on the labor relations of the industry, centering chiefly on General Electric and Westinghouse, including a discussion of wage rates, benefit plans, and labor costs. A chapter is devoted to the impact of foreign competition, and a final chapter sums up the whole in glowing (incandescent?) terms.

In all, the result is unsatisfactory. It probably is just not possible to write a critically objective book when one builds it (p. xxii) on the base of a report written for one of the "private special interests" with which the book is concerned (Westinghouse Electric Corporation). From Backman one gets these impressions: the industry is concentrated, but not much more so than many others, and concentration would be no index of monopoly anyway even if concentration ratios were any good, which they aren't; there are substantial barriers to the entry of new firms but this does not prevent vigorous competition, as witness the "highly competitive automobile industry" (p. 73); there are no

precise yardsticks with which to measure the effectiveness of competition (p. 58), so why get excited about it; nor with which to evaluate the "adequacy" of profit margins (p. 273), so who can say that they may be larger than "necessary."

Yet more: prices have risen more than for industry generally over the post-war period but not more than is justified by rising wages; productivity per production man-hour, meanwhile, has risen faster than in most other manufacturing industries, and the ratio of production workers to total employees has fallen sharply; wage rates are almost identical to those of industry generally and have risen no faster. (Try reconciling these facts on your G.E. computer!) And further: depreciation charges have been inadequate, net worth is understated, and profits are overstated (p. 259 and following). But here the author is only restating the chronic complaints of the business community and begins to depart from the kind of original conclusions illustrated above. The last paragraph on page 277 summarizes the preconceptions he has failed to validate and draws out a final grand generalization that does not emerge from the evidence.

To be more specific, Backman believes that if some authorities (Kaysen and Turner) find a concentration ratio of 33 per cent for the eight largest firms in the industry and another finds a ratio of 70 per cent (Bain), the range is so wide as to have *no* meaning (p. 93). But are not both these ratios indicative of a concentrated market structure? Backman points to the shifting of positions in the "big four" as evidence of shortcomings in concentration ratios (p. 97); but does it matter to the buyer if Westinghouse supplants G.E. in a product line if he can secure the product only from one of these two? The author states that little of the growth of the major firms was attributable to mergers (p. 99); but by 1892 the mergers of the 1880's had resulted in two giants who held 90 per cent of the market (what was there left to merge?).

The analysis of company and plant concentration is faulty (p. 105). If cost per unit is fairly constant over a wide range of *plant* sizes, more firms with more plants are preferable to fewer firms and plants and technological requirements do not explain concentration. Backman cites the top position held by the industry in research and development expenditures, but is this necessarily "good"? Unit labor costs rose only 6.3 per cent in the eleven years 1947-58 but Backman calls this a "sharp rise in unit labor costs . . . wage inflation" (p. 246). His discussion of the function of profits simply reflects confusion (p. 251 and following).

The disdainful neglect of the great price-fixing conspiracies is, of course, the chief fault to be found with the book. But with all its sins of omission and commission, the work of Backman and his associates provides a considerable volume of source material for those interested in this specific industry and, if the text is read with tongue in cheek, those who quote from the work may not be caught with foot in mouth.

Those who followed the developments in the electrical manufacturing industry as reported in the entertainment, obituary, comic, and, occasionally, the financial pages of the newspapers, beginning with (at least) the award-

ing of turbine contracts by TVA to foreign producers in 1959 and on through the grand-jury investigations and indictments, the pleadings, the sentencing in February of 1961 and the subsequent hearings of the Kefauver Committee, will find nothing new in the Fuller book.

This well-written little volume, full of adjectives appropriate to the muck he is raking, is worth reading for those who first were made aware of the developments by the headlines of February 1961. It may very well be substituted for Chapter 5 of Backman's study: "Price Policies and Price Practices," and, being in the narrative form, may take no longer to read. Fuller is properly exercised by and recognizes the deep significance for the viability of the market economy of price-fixing, market-sharing, bid-rigging and all the rest, and makes suitable recommendations for public policies. We need more angry men.

Die Konzentration in der Wirtschaft. Verhandlungen auf der Tagung des Vereins für Sozialpolitik, Gesellschaft für Wirtschafts- und Sozialwissenschaften in Bad Kissingen 1960. Edited by FRITZ NEUMARK. Schriften des Vereins für Sozialpolitik, Gesellschaft für Wirtschafts- und Sozialwissenschaften, N.S. Vol. 22. Berlin: Duncker & Humblot, 1961. Pp. 395. DM 36.60.

This volume represents the proceedings of the 1960 meeting of the Verein für Sozialpolitik. It contains five major papers, five brief papers on special issues, and a round-table conference on the measurement of concentration. The major papers deal with: the sociological aspects of concentration (Edgar Salin); concentration and the firm (Karl Hax); concentration and competition (J. H. Müller); causes of and remedies for concentration of wealth (Carl Föhl); concentration and social policy (Hans Achinger). The special papers deal with: growth and concentration (Karl Brandt); technological concentration (Waldemar Wittmann); concentration and fiscal policy (Heinz Haller); integration and concentration (Reinhold Henzler); concentration and adjustment to changing market conditions (Theodor Wessels). Each paper is followed by a discussion. The participants in the round-table conference were: M. A. Adelman; J. M. Blair; Karl Brandt; Gerhard Fürst; Hans Guth; P. E. Hart; Heinz König; Jürg Niehans; Günter Ollenburg; Gideon Rosenbluth. The contributions of Adelman, Blair, Hart, and Rosenbluth are in English; all others are in German, the language of the conference.

The reviewer of an anthological volume cannot be expert in all or even in most of the areas covered, and cannot summarize, let alone discuss, every contribution in the space available to him. In purpose this volume is comparable to *Business Concentration and Price Policy* (A Conference of the Universities-National Bureau Committee for Economic Research, Princeton 1955). The German volume covers more ground than the U.S. volume. The concept of concentration is here broadened so as to include concentration of personal wealth (Föhl) and of power within the firm (Hax). Moreover, the contributions consider, in addition to the economic aspects, also the socio-

logical, historical, and to some extent ethical aspects of concentration. On the other hand, with the notable exception of the round-table conference on measurement, the treatment is on the whole less technical than in the U.S. volume.

Previous to the meeting, three volumes of monographs on concentration had been published on: (1) the present degree of concentration; (2) causes of concentration; and (3) the effects of and the problems of concentration. Apparently the papers presented at the meeting are to some not well-defined extent based on these materials. This presents certain difficulties. Aside from three statistical tables—the gainfully employed population in 1958; the income distribution in 1958; and the formation of wealth from 1950 to 1959; all for West Germany (pp. 193-95)—little empirical evidence is explicitly given in support of the hypotheses advanced by the participants. Throughout the volume there are frequent references to the *Materialbände*, but mostly to the volumes in general rather than to specific information. Equally casual reference is also made to U.S. empirical evidence.

The contributions of Salin and Föhl represent as it were the two poles of the discussion, not only because they reach opposite conclusions but also because much of the rest of the volume is concerned with the elaboration of ideas contained in these two papers. Salin argues that concentration is not only inevitable, but that increased concentration is necessary if the free economies of the West are to be and to remain as efficient as the growing economies of the East. Föhl feels that the concentration of wealth which is the basis of business concentration can be efficiently controlled in a free economy. He agrees that the free enterprise system offers the opportunities for concentration of wealth and economic power. Essentially, however, these opportunities are exploited by individuals who, while intelligent and able, are at the same time obsessed with greed for wealth and power. Föhl suggests that these individuals should be distinguished from the creative enterpriser (p. 168). Since he sees in the concentration of incomes the main source of the concentration of wealth, he proposes a very complicated system of fiscal measures by which the incomes of wage-earners should be increased and the resulting increments channeled into savings. Thus the wage-earners would become owners of wealth and both the distribution of incomes and of wealth would become more equal. Throughout the argument Föhl apparently assumes a marginal propensity to consume which declines rapidly with increasing income (e.g., p. 164).

All the contributors who deal with it at all consider self-financing to be one of the most potent sources of concentration. Consistent with his general position, Salin welcomes self-financing (pp. 20, 21). Hax sees in it a source of the superiority of the large enterprise (p. 88). Föhl (p. 185) and Haller (pp. 294, 296) propose fiscal measures to restrict self-financing. In contrast to this position, John Lintner and J. K. Butters in their contribution to *Business Concentration and Price Policy* (Effects of Taxes on Concentration), submit empirical evidence to the effect that self-financing, at least in the United States, is most important in and for the small firm and thus counteracts concentration. It is therefore regrettable that the German authors do not

refer to the empirical evidence on which their reasoning is based and thus leave the reader with the impression that at least some of it is of an a priori nature.

This reviewer is not qualified to pass judgment on the discussion of the technical problems of measuring concentration. On the whole, this discussion seems to have aimed at reviewing the present state of affairs rather than at making new contributions. As a review of the available measures and of their properties, applications, and limitations, this last part of the volume is of very real value.

The U.S. reader looking in this volume for new contributions to the economic theory of concentration and of market behavior will be disappointed. On the other hand, the diversity of approach and the inclusion of many aspects usually neglected in narrowly theoretical analyses make these essays rewarding reading. At the very least, they offer an excellent survey of current German thinking on concentration.

Design of Water-Resource Systems—New Techniques for Relating Economic Objectives, Engineering Analysis, and Governmental Planning. By ARTHUR MAASS, M. M. HUFSCMIDT, AND OTHERS. Cambridge: Harvard University Press, 1962. Pp. xviii, 620. \$12.50.

Here is the long-awaited product of the Harvard Water Program. Financed by generous grants from the Rockefeller Foundation and by support from public water agencies, an interdisciplinary group of Harvard faculty members has conducted seminars and research over a five-year period dealing with the complex questions of design and operation of water resource systems. The program has attempted to integrate economic, engineering and governmental analysis and to devise new techniques for planning multipurpose, multi-unit water systems. Primary concern has been with methodology for design criteria, programs, and evaluation. The results, as exhibited by this volume, clearly indicate that these efforts were not wholly successful. Nevertheless, this study should be viewed as a substantial achievement in the methodology of system design with useful applications much beyond the confines of water resource systems.

Actually, the book is not a cohesive product. It combines two separate types of material. On the one hand, it contains a series of essays, each rather brilliant and quite self-contained; on the other hand, many of the chapters constitute interesting research reports of a "how we did it" nature. The multiple, interdisciplinary authorship has given the book a great deal of breadth but also a certain amount of unevenness in level of analysis and range of subject matter. For example, one chapter contains over sixty pages of detailed programming notation, in "cook-book" fashion, for a high-speed digital computer; yet the entire section devoted to the political process and govern-

mental factors and their influence on system design is less than forty pages in length. Because the design problem here assumes, for the most part, a public planning process it might have been desirable to have expanded the treatment of governmental structure and to have placed computer programming instructions in an appendix.

Designs of water systems in this study are largely restricted to systems and techniques for manipulating physical structures for handling water flowing in surface channels. Operation of ground water systems, problems of water quality, re-use and recirculation of water, and nonstructural alternatives such as flood-plain zoning are among a number of aspects of water management that are not examined. The question of pricing policy for water resources is passed over because "potential system revenues play no part in ranking designs in terms of efficiency." Instead, revenues are considered "simply as transfers of income from direct beneficiaries to the nation at large" (p. 38). The role of prices in promoting allocative efficiency is thus underplayed. Because of this it is strange that alternative rationing devices were not examined.

Robert Dorfman and Stephen A. Marglin each contribute two essays which will be of general interest to economists. In an early chapter Dorfman provides a succinct review of production theory, net benefit functions and decision theory. Some readers may get a chuckle out of his conclusion that "the problem of uncertainty is clouded by uncertainty" (p. 158). I suspect that Dorfman has made an important pioneering contribution in his second essay where he applies mathematical programming to problems of increasing complexity in preliminary stages of design for water projects. A three-season example with uncertainty is reduced to a standard linear programming problem involving sixty constraints and the system is simulated for a fifty-year period. Apparently, such simplified models can serve as a basis for more elaborate simulation analysis.

Marglin attempts to show how the design of specific water systems can take into account the twin objectives of efficiency and income redistribution. Methods of describing efficiency in terms of income redistribution constraints (and vice versa) are handled with considerable ingenuity. Marglin even sets forth the concept of a redistribution interest rate, which could well be negative indicating that the efficiency value of redistribution benefits increases with time. Although the Lagrangian multipliers and shadow prices derived are rather straight forward, there is much left unsaid or simply assumed about the whole range of philosophical considerations (and political implementation) of the twin objectives. Much of the neatness of the analytical solutions is also based upon such a restriction of the scale of redistribution that the general structure of price ratios is not appreciably affected. If the scale of income redistribution were large, it is not at all clear what would be meant by efficiency losses as consequence parameters.

In another chapter, Marglin develops his own concept of a social rate of interest based upon the hypothesis that there is a large degree of generalized concern on the part of individuals for future generations (in the abstract) that cannot be satisfied by the market mechanism. This psychic preference,

he argues, can be satisfied only through collective coercion to increase the rate of public investment. Some of this reasoning is plausible but unsupported by empirical evidence; some of it appears to be defective. This section of the book will cause many readers to choose up sides. In the case of capital rationing, Marglin proposes evaluation of public investment at the social rate of interest coupled with the use of a cut-off benefit-cost ratio above unity which would reflect the opportunity costs (reinvestment of the throw-off) of *all* investment, public and private. Marglin, therefore, is not guilty of committing the crude error that plagues many other proponents of the social rate of discount; his formulation clearly takes into account the marginal productivity of private and public investment assumed to be displaced by the particular public project under consideration. Furthermore, these opportunity costs are automatically converted to a common time-stream basis so that use of the initial low discount rate does not influence the ranking of alternatives possessing varying time streams. If consistently followed, Marglin's formulation would lead to the same ranking of projects that would obtain if one were to discount by the marginal productivity of capital in the first place. Special attention is also given to the dynamics of development where postponement of construction will often increase the present value of net benefits.

Probably the most important contribution of the Harvard Water Program is the development and application of two techniques of system design—simulation of a simplified river basin system on a high-speed digital computer and the development of mathematical models for river systems. The chapters describing these techniques are exciting and suggestive, not just for water systems but for systems analysis in general. These two techniques were used in planning the design of a simplified river basin system containing twelve design variables. With the aid of computers, simulation models were designed by Harold A. Thomas and Myron B. Fiering to synthesize a record of 510 years of stream flow. Flow-distribution parameters for cross-correlation of synthesized flows were established by use of bivariate linear-regression models. Because the economic design period for the system was assumed to be 50 years, the 510-year period, allowing 10 years for a "warm-up," permitted use of 10 hydrographs. The variation in the ten sets of results offered a more reliable estimate of expected net benefits than could be expected from estimates based upon actual hydrology.

Mathematical models of two types are presented in the book. Both employ data derived from the simplified river system and both use linear programming techniques. One model is called "multistrukture" (developed by Dorfman) and the other is titled "stochastic sequential" (developed by Thomas and Watermeyer). The basic difference lies in their handling of the stochastic component of stream-flow. The stochastic sequential model can optimize only for output and operating procedure. Choice of reservoir size must be made by sampling techniques. The multistrukture model optimizes for all three variables in combination, but it can not handle overyear storage or linkages between segments of the system over successive time periods.

To Arthur Maass fell the concluding task of relating system design to the

political process. The result is that Maass, as did most of the other authors before him, wrote an essay which is instructive and well-taken but not particularly integrated with what has gone on before. Maass sets up a model of a modern democratic state and then proceeds to show that public water planning in the United States violates parts of the model. What this might mean if one were not to accept the particular model is not altogether clear. Maass then closes with some very interesting observations regarding art of system design for large river systems. He points out that techniques proposed in the book cannot be intensively applied to very large river systems such as the Mississippi River. This matter might well have been taken up in extensive fashion much earlier in the book (rather than waiting until seven pages before the end). As a solution to the large river basin case, Maass proposes the techniques of "skeletonizing" and segmentation, i.e., conceptually aggregating related structures on tributaries or viewing segments as separate units and then linking them together. Along with this proposal is the warning, however, "that we do not have an adequate definition of a major segment; the data necessary to define it have never been assembled" (p. 599).

All of this means that the simplified river basin is really simple and that the techniques set forth in this volume, powerful as they seem to be, are still in their infancy.

Economic Redevelopment in Bituminous Coal: The Special Case of Technological Advance in United States Coal Mines, 1930-1960. By C. L. CHRISTENSON. Cambridge, Mass.: Harvard University Press, 1962. Pp. xxi, 312. \$7.50.

To judge from the accounts in such secondary sources as undergraduate textbooks, the image persists among academic economists that the bituminous coal industry of today is little different in structure and market behavior from what it was twenty, thirty, or even forty years ago. In the 1960's as in the 1920's and 1930's, that is to say, it is held that the industry is confronted with shrinking markets, persisting excess capacity, a lagging rate of technological advance, and periodic outbreaks of "destructive" price competition, among other things. It is said to be, in a word, "sick."

Among the handful of us who have examined this image at first hand in the period since the second World War, the suspicion has grown that it is badly distorted. Stated affirmatively, we have individually and severally suspected that the industry is well-launched upon a process of redevelopment, one which promises to result in significant changes in its structure, and in the conduct and performance of its firms. This opinion, not heretofore put to a thoroughgoing test, has now been strongly confirmed by one of the industry's leading scholars, C. L. Christenson of Indiana University.

Christenson's main objective, his point of departure for the volume under review, is to "measure the amount of [technological] change, identify its location, and determine the character of the social cost involved in the achieve-

ment" (p. 2). But to get at these matters, he finds it both advisable and necessary to inquire into a variety of other issues, among them (a) the present and prospective role of bituminous coal in world economic development, (b) the structure of the United States coal industry, (c) recent changes in coal consumption patterns and their impact upon the industry's structure, the operation of mines, the boundaries of bituminous submarkets, and the timing of consumption, (d) the relationship between total and per-mine productivity, on one hand, and wage differentials, on the other, (e) trends in employment and earnings of labor by geographic location, size and type (surface or underground) of mine, and (f) the factors promoting technological change.

So varied are the relationships which Christenson explores, so extensive are the data which he brings to bear, and—unhappily—so frequently does he fail to make clear the links between one point and another, that it is well-nigh impossible cogently to summarize his arguments and conclusions. But these of the points he makes certainly deserve brief mention:

1. Bituminous coal, particularly that stored in the generous reserves of the United States, has an important part to play in satisfying the rising world demand for fuel. Both in absolute and relative terms there is a good possibility that its share of the market will rise over time. But, "To achieve and to maintain a position of increasing responsibility for the spread of industrialism in the Western world the bituminous coal industry of the United States will have to rely upon continuing improvements in mining, transportation and in the consumer's use of its product to match the performance of other fuels" (p. 30).

2. "So far as the bituminous coal industry is concerned, its structure is compellingly determined by geology" (p. 31). This is mainly to say that the location and thickness of coal seams, and the quality of the product profoundly affect not only the costs of mining but also the conditions of entry into the industry, size of mines and mining establishments, character of ownership, and financial patterns, among other things. Central to this generalization is what Christenson terms the process of "discriminating selection," by which he means that coal-mine operators pick and choose, according to their respective market objectives, among the many types and qualities of bituminous and the many degrees of seam thickness which are available. He finds, to cite one example, that the "integrated" or "captive" mines, which are able to maintain more continuous mining operations than their commercially-oriented counterparts, tend to operate in thick-seam locations; and the evidence indicates that the thicker the seam, the greater (by and large) is the average daily tonnage per mine, the larger the number of mine operating days per year, and the greater the annual tonnage per mine.

3. As compared with the situation twenty and more years ago, the pattern of coal consumption in the United States has changed markedly. One result of the decline in use of bituminous for home and commercial heating and the rise in its use by electric utilities and industrial consumers has been a marked reduction in seasonal fluctuations in coal demand. Another implication of the realignment of consumption patterns is that, because the utilities tend for various reasons to buy the bulk of their coal from multi-unit min-

ing companies, they are promoting an evolutionary shift in market structure toward ever-fewer and ever-larger mining firms. More important yet, Christenson finds considerable evidence that coal is increasingly being sold in a network of sub-markets, each characterized by a differentiated product, price and wage differentials, and barriers to entry by new firms.

4. Although some thin-seam mines have been mechanized, the rate of technological change appears to vary directly with the thickness of the coal seam. Again, in other words, geological factors are of prime importance in the redevelopment of the industry.

5. Despite industry-wide bargaining, there are differentials throughout the industry in both wage rates and average hourly wages. The differentials appear to be very closely related to variations in productivity (measured both in physical and value terms), variations which themselves stem chiefly from geological factors.

6. Though wages have risen substantially in the postwar period, labor cost as a percentage of mine-realization price has been falling. This is a result largely of productivity increases associated with mechanization, which has been prompted in part by changes in the level and the structure of wages—notably the adoption by the industry of a welfare plan for miners financed by a flat-rate royalty on output. It is equally noteworthy that rising productivity is closely associated with declining employment in the industry.

7. Firms mechanize principally in order (a) better to compete with sellers of substitute fuels, (b) better to compete with other coal mines enjoying lower transportation costs to the relevant markets, and/or (c) better to compete with mines working seams of greater thickness and of higher-quality coal. Pressure exerted by the miners' union is acknowledged to be of some importance too—although on this point Christenson is ambiguous.

8. The major social cost of coal's economic redevelopment is a decline in employment which in too many of the nation's mining regions has not been offset by alternative employment opportunities.

As was suggested at the outset of this review, little new ground is broken in this book. But it is still an important piece of work, not only because it weaves together a vast number of strands spun (in whole or part) by other researchers but also because it skillfully picks up numerous previously dropped stitches. It is not, however, without flaws, chief among which is that the logic is too often obscure and the language too often turgid. The luster of Christenson's scholarship is, in other words, dulled by his expository deficiencies.

MORTON S. BARATZ

Bryn Mawr College

Khozraschet v kolkhovakh (Economic Accounting in Collective Farms). By N. P. SOBOLEV. Moscow: State Publishing House for Agricultural Literature, Journals and Posters, 1961. Pp. 224.

Not so long ago, the existence of costs in collective farm production was denied by Soviet economists. According to the 1961 program of the Communist Party of the Soviet Union, economic or cost accounting is to form the basis of all productive activity of every such farm. In the meantime, many

though not all institutional obstacles to the introduction of this form of "socialist management" (the multiple system of farm prices, payments in kind to various state institutions) have been removed in the drive to increase the level as well as the efficiency of Soviet farm output.

The author of the volume, which is based primarily on practices adopted by four collective farms located in the central black-soil area, aims above all at wide dissemination of practical experience acquired in this rather complex field. Roughly one-half of the book is devoted to the application of cost accounting within the collective farm itself, i.e., in its operational subdivisions, such as complex brigades, field brigades and livestock farms. It is only natural that this should be so, since the complexities of collective farm management are growing directly with its size as a result of continuing mergers; furthermore, the majority of the farms have as yet failed to introduce an internal system of economic accounting. At the same time little is said about the operation of the collective farm, as such, on the basis of economic accounting. That, too, is not surprising: a *khozraschet* enterprise is assumed to cover its expenditures by its income, while losses on the collective farm are borne by its members.

Sobolev discusses extensively the various ways of setting up cost accounting targets for the operational subdivisions of the collective farms. At first he appears to be begging some fundamental problems of valuation in the calculation of farm production costs: alternative methods of pricing labor inputs, productive expenditures in kind, and distribution of products to farm members are merely listed (p. 27). Although he finally tackles them at length (pp. 95-115), the results are far from satisfactory. The author appears to favor the valuation of labor inputs not in terms of average state farm wage rates, but rather in terms of actual expenditures for labor incurred by the farm. It might be useful here to indicate the order of magnitude of the difference between the alternative methods: in 1959-60, a collective farm labor day (*trudoden*) in the Tatar autonomous republic, priced at state farm wage rates, was given a value of 17 (old) rubles. Actual collective farm payments were 9.48 rubles in 1959 and 11.49 rubles in 1960. This, however, is not the main issue. Since collective farm labor is still rewarded in the form of residual shares, the advocated procedure may lead (and in some instances has indeed led) to rather paradoxical results. Thus, a rise in the labor payments resulting from a *decrease* in real labor expenditures per unit of output may well show up in the accounts as an *increase* in the production cost of a given unit of output.

Sobolev's views on this matter appear to be inconsistent with his preference for the valuation of production expenditures in kind. In this connection, he suggests the use of production costs rather than the state purchase prices (a procedure advocated by other Soviet economists). Otherwise, we are told, a reduction in the cost of producing "feed would not be reflected in the [level of] production costs of animal products" (p. 98).

The problems raised here are truly basic: as long as collective farms continue to reward labor in the customary manner, the correct valuation of labor inputs will remain a difficult and elusive problem. This is undoubtedly a

partial explanation of the recent drive to introduce fixed, wage-like, labor payments in the collective farm sector. In any event, the thorny valuation issues readily explain the position of some Soviet economists who maintain (correctly in our view) that in such conditions it is impossible to introduce the full system of economic accounting and that only some of its elements may be brought to bear on the problem of efficiency of production on the collective farms.

Since the use of state farm wage rates to value collective farm labor inputs is not without its own pitfalls, it may well be that a system of double book-keeping is in order here, with one calculation using state farm wage rates to be used at the collective farm level, and another using actual collective farm labor payments at the brigade or intrafarm level. A veiled hint to this effect appears on page 97. It should also be noted that in some instances it might be necessary to evaluate the performance of a brigade in terms of planned rather than actual labor-day values; otherwise the economy of real labor inputs in the brigade might again be reflected in the accounts as an excessive use of labor measured in money terms.

In view of the fact that the economic use of farm capital and the establishment of norms for the use of the capital factor are listed as the major direction for the future development of economic accounting on the collective farms, it is not quite clear why the author believes it unnecessary to include amortization norms among the targets listed for the various brigades (p. 89).

About a quarter of the book is devoted to the problem of rewarding farm members for the achievement (or overfulfillment) of cost accounting targets. In the present state of affairs, Sobolev favors a division of the total "wage fund" of the collective farm into three categories: a basic labor payment fund, a fund of supplementary payments for fulfillment of "especially important tasks" and for achievement of high quality of output (about 10 per cent of the total), and a fund of material incentives for achievement of cost accounting targets. Although he is not clear as to the relative magnitude of the last category, it appears from his discussion of the prevailing practices that it could amount to as little as 15 and as much as 40 per cent of the total wage fund. These sums should be distributed according to results revealed by the indicator of lowered production costs. But here (as elsewhere in the book) the author does not rule out the use of more primitive indicators (net income per labor day, gross output per labor day) as long as the farm is unable to employ a more sophisticated system of cost accounting.

Clarity of presentation is not one of Sobolev's virtues, and he received little help from his editors in this respect. A less sparse use of subtitles and separation of his conclusions from the illustrative material would have made the book more useful to the harassed collective farm chairmen, planners, economists and accountants.

To the Western specialist, the book includes rewarding bits of information on Soviet agriculture generally. For example, it is gratifying to see a confirmation of our deductions that collective farm members "usually exert a strong pressure" on farm planners to secure an equitable distribution of such crops as sugar beets among the various brigades (p. 71). Farmers directly partici-

pating in the production of this crop receive large quantities of sugar at a privileged price of .38 rubles per kilogram, as compared to the retail price of slightly over 1 ruble a kilogram. Similarly, it is useful to know that purchases of farm machinery by collective farms in 1958 occurred in a somewhat haphazard way and led to uneven distribution of tractors between farms (in the Voronezh oblast, some farms acquired one "accounting," or 15 HP, tractor per 150 hectares of arable land, while others purchased a similar tractor for 218 hectares of arable land).

The Economics of Subsidizing Agriculture: A Study of British Policy. By GAVIN McCRONE. Toronto: University of Toronto Press, 1962. Pp. 189. \$3.50.

The coverage of this book is considerably broader than the title implies. While its title might cause one to expect a more technical analysis of the effect of agricultural subsidies on supply, distribution of costs, and consumer welfare under British policy, it perhaps devotes less emphasis to these topics than to a broad analysis of agriculture in a framework of economic growth and world markets. The latter is, of course, a necessary foundation for analysis of any major industry in Great Britain.

McCrone has provided an interesting perspective with regard to British agriculture and the postwar and interwar policy surrounding it. He provides insights which will prove interesting to persons not currently acquainted with the details of European agricultural development and the particular problems stemming from economic growth, Common Market organization and specific national agricultural policies. He has developed some new understanding and alternative analyses of the agricultural sector even as related to economies other than Great Britain. Some conclusions are of interest particularly in the United States where even larger subsidies and problems of policy have been involved in the agricultural sector.

The first of 12 chapters is devoted to the role of agriculture in the British economy. He presents figures illustrating the somewhat unique position of agriculture in New Zealand, Australia and Great Britain where agriculture's share in national income exceeds this industry's percentage share in the national labor force. Of interest relative to U.S. agriculture and its current over-expansion, he explains in Chapter 2 the contraction of British agriculture following the Napoleonic wars and its consequences in causing farm-income depression and a restrained growth in agricultural efficiency. He attributes part of the small role of agriculture in the British economy to the classical emphasis on free trade and *laissez faire*. Later, he questions the unrestrained application of these policies. He points out that while agriculture contracted under these policies, the adjustments did not bring a prosperous farm industry.

Differences between Britain and other European countries in respect to policies used in supporting farm commodity prices and income are discussed.

Professor Wendt has produced a study intended to cast some light on the comparative performance of one sector of the economy, namely housing. This analysis of postwar housing policies in the United Kingdom, Sweden, West Germany, and the United States, is based upon a year of first-hand research carried out by the author in Western Europe during 1958. It is clear that Wendt acquired not only a thorough knowledge of housing policies and conditions in the countries on his tour but also immersed himself in the abundant literature on housing in the various countries.

The book is particularly commendable for the candor of its views and the author's willingness to draw firm policy conclusions from his data and observations. Statistical tables are used to support rather than to replace personal judgment and opinions. For example, the author recommends our adoption of some policies, especially income tax subsidies, which Western Germany found effective in stimulating housing:

Rapid amortization for federal income tax purposes of private investments in low-income rental housing should furnish a strong incentive for private investors to build housing for such groups. Because of the strong preference for ownership housing in the United States, provisions for rapid amortization subsidies should be extended to owner occupants unable to afford housing of acceptable standards without subsidy. [P. 269.]

Yet for all its merits, the book is in some ways disappointing. Its contribution to improving future housing policies in the United States is likely to be limited for several reasons:

1. Both in Sweden and the United Kingdom, two of the three Western European countries studied, the direct participation of government in the housing market has been greater than would be tolerated in the United States. For example, in Sweden more than 95 per cent of new dwelling construction in recent years was built with the aid of state financing. Moreover, the strong cooperative movement in Swedish housing is unlikely to find much emulation in the United States. So far as the United Kingdom is concerned, the author points to numerous weaknesses in postwar housing policies which, it is true, can be studied with profit in the United States. On the whole, however, housing policies pursued by these two countries are either inapplicable to conditions here or at best suggestive in a negative way.

2. Wendt is particularly impressed by the effectiveness of postwar housing policies in Western Germany which, he believes, not only succeeded in rapidly increasing the quantity and quality of the housing stock but did so while maintaining a remarkably stable price level. Reliance was placed on the stimulation of private savings for housing, direct public lending and subsidies, low-interest-rate loans, and generous tax incentives. Undoubtedly, economic liberalism played its part. But one factor of great importance in the relatively inflation-free growth of Western Germany has been widely ignored, in this book and elsewhere. Wage and price stability reflected to a large extent the tremendous influx of labor from East Germany. This influx not only contained the wage-price spiral suffered by other countries but provided the labor force needed for economic reconstruction and expansion. If this analysis is correct, Germany's economic "miracle" may look different in the future

as the exodus of East Germans (12 million between 1945 and 1960) comes to a stop. The experience of Western Germany illustrates the difficulty of isolating the impact of the myriad of economic policies on the market for housing.

3. One other consideration is likely to limit the usefulness of this book in devising future housing policies for the United States. Recent years have brought some basic structural changes in the market for residential construction. Postwar policies designed to spur construction are no longer suitable for the future. The tremendous backlogs of demand for housing, accumulated not only during the years of war but during the earlier years of depression, have been satisfied. As Saul Klamman pointed out in a recent talk, builders will need to "develop and aggressively market an appealing product that will stimulate demand of buyers already well housed, rather than buying out of desperation as in former years. Opportunities in the replacement market rather than in the new house market need to be imaginatively exploited. In addition, new markets for elderly people, for low and middle income groups, for those displaced by urban renewal and highway construction, for nursing homes, and for minority families will require special skills for profitable ventures."

Wendt has provided, in Chapter 6, a useful evaluation of United States housing policies. He is justly critical of the proliferation of housing agencies, their divided responsibilities, and their generally poor administration. He criticizes the failure of the federal low-rent public housing program. He urges the creation of a secondary conventional mortgage market along lines developed recently in much greater detail by Jones and Grebler.¹ He rejects, however, the widespread view that federal housing credit policies have led to cycles in residential construction. On this issue, many housing authorities would disagree sharply, blaming the ceiling on Federal Housing Administration and Veterans Administration loans for systematically shutting off the flow of mortgage credit in periods of strong economic expansion. But even this issue has receded in importance with the maintenance of easy credit conditions and the large flow of savings into the mortgage market during the economic recovery of 1961-62.

Anyone concerned with housing either as student, investor or administrator should read this book. He will disagree on many points but he will not fail to be stimulated.

Labor Economics

Employment Objectives in Economic Development—Report of a Meeting of Experts. Geneva: International Labour Office, 1961. Pp. xi, 255. \$2.75.

The report on *Employment Objectives in Economic Development* was sponsored by the International Labor Office and was prepared by a group of

five economists from Brazil (Campos), Canada (Higgins), Italy (Marsan), Poland (Pajestka) and India (Raj). The ILO asked these economists "to make a thorough analysis of the problems of employment creation . . . and to suggest appropriate measures for the expansion of employment opportunities" (p. iv).

The volume is divided into two parts. The first 140 pages contain the report of the experts, and the balance is a summary presentation of economic development in eleven countries since the Second World War plus brief excerpts from a discussion of an ILO Committee on Employment Problems.

Although the name of Malthus is never mentioned in the report, the spectre evoked by him permeates the volume. World population, estimated at about 3 billion, has doubled during the 20th century and is expected to quadruple by the year 2000. Between 1925 and 1950, world population increased at the annual rate of 1.1 per cent, but during the next decade the comparable rate of increase rose to 1.5 per cent. And the increase has been most rapid in underdeveloped countries where the problems of subsistence and survival are most acute. Economic growth and demand for new jobs in most of the world have not kept pace with medical technological developments. During the past decade alone mortality rates in some underdeveloped countries have dropped by half.

This is the backdrop against which the ILO panel of experts analyzed economic growth in underdeveloped countries and attempted to propose the best methods for generating new employment. In India, Pakistan, Japan and other countries the panel found that the estimated additional jobs that would be created under the respective economic plans or projections would barely suffice to absorb the new entrants into the labor force. As the Queen said to Alice, "Now, here, you see, it takes all the running you can do, to keep in the same place. If you want to get somewhere else, you must run at least twice as fast as that!"

The underdeveloped economies are characterized by a dualistic structure. The traditional sector is predominantly based on agriculture; the second is a slowly growing industrial complex. The livelihood of the bulk of the population is dependent upon the traditional sector characterized by low capital investment and labor-intensive production. The ILO panel sees little hope for the generation of additional employment in this traditional sector of the underdeveloped economies. Capital investment in this sector would raise the living standard of few but tend to transform underemployment to unemployment of many more. The panel favors land reform and improvements in agricultural productivity. But in those countries where the cultivated land has been redistributed among the agricultural workers, the average farm has been limited to less than two acres per family. Even with improved productivity, the small landowners are condemned to bare subsistence.

The hope of the underdeveloped countries lies, therefore, in accelerating the growth of the modern sectors of their economies. The report suggests that an adequate rate of growth would require that at least a fifth of national income of underdeveloped nations should be allocated to new investment. Foreign capital is essential to achieve this rate of investment. The report also

favors "bold" fiscal policies and "appropriate" wage policies to restrain rising consumption resulting from increased productivity in order to channel the additional income into investment.

Expanded secondary and higher educational facilities are normally prescribed as an essential part of an economic program for underdeveloped countries. But the case studies indicate that in most of the underdeveloped countries the level of unemployment remains high among the educated groups, since the relatively slow economic growth fails to generate enough professional and technical jobs for the high school and college graduates who refuse to settle for manual labor.

The report is intended as a manual for policy-makers and planners in underdeveloped countries. It is perfectly adequate in summarizing the economic problems facing underdeveloped countries, but, being the product of economists exclusively, it falls short in considering the socio-cultural factors that affect economic development.

The report also suffers from the antiseptic quality common to many ILO studies. No consideration is given to political factors. It deals with economic development in terms of universal verities unaffected by political institutions.

Public Policy and Collective Bargaining. Edited by J. SHISTER, B. AARON, AND C. W. SUMMERS. Industrial Relations Research Association Publication No. 27. New York: Harper & Row, 1962. Pp. viii, 248. \$4.50.

This is a multiple-author volume dealing with a number of contemporary and crucial issues in labor-relations law. Included are employer free speech (Benjamin Aaron); the duty to bargain in good faith (Robben W. Fleming); union security (Paul E. Sultan); picketing and boycotts (Donald H. Wollett); antitrust and collective bargaining (George H. Hildebrand); regulation of internal union affairs (Joseph R. Grodin); and a comparison of United States and Canadian experience (Harry D. Woods). Preceding these essays is an excellent contribution by Douglass V. Brown and Charles A. Meyers providing the historical and theoretical framework for United States labor-relations law.

Since the volume does not treat other vital areas of public control, a condition which the editors fully acknowledge, it is not suitable as a basic textbook for a labor law course; but the generally high quality of the essays is such that it deserves a place on the reading lists for undergraduate and graduate students in such courses. We are told that the volume is not directed at the labor law specialist or for the layman, but is pitched for the "informed observer." On this score it must be reported that the essays are not of equal caliber. Some treat the material in a routine way, largely duplicating material found in the ordinary labor law textbook with which at least some "informed" observers should be familiar. On the other hand, in others there is fresh analysis which warrants the attention of the specialist, and particularly of those actively engaged in shaping the law of labor relations.

With full deference to the editors' choice of subject material, it is still

regrettable that the volume lacks a treatment of the effort of the national administration to influence the substance of collective bargaining through the so-called "guideline" approach. This development is packed with controversy and implications. Inferentially, however, there is some relevance to this contemporary problem in the case of Woods' contribution on the Canadian scene. Those who applaud the Kennedy-Goldberg approach, and would welcome even more direct government intervention, should heed his conclusion that in the Canadian provinces where such intervention has been extreme, the program has resulted in the "emasculatation of collective bargaining" (p. 236). Indeed, after a most penetrating and brilliant analysis, Fleming concludes that the essence of his argument is that "as long as the parties are in good faith, and the demand is legal, the NLRB and the courts should keep their hands off" (p. 84). Statism, he suggests, dulls the opportunity for and the incentive of private parties to use the collective bargaining process effectively to meet the challenges of the future.

A strong point of the volume is that in most of the essays description is subordinated to analysis and recommendations. Sultan is concerned that "harmony" and "maturity" in relations between employers and unions may result in the abuse of dissident minorities, though he apparently does not believe that "right-to-work" laws provide the answer to this problem. Hildebrand rejects the general expansion of antitrust laws to organized labor, though he believes if such a program is confined to specific abuses "such as make-work or exclusion from the product market, antitrust could yield some modest benefit" (p. 179). On the other hand, analysis and recommendations are not contained in the Grodin essay. His research shows that much of the Landrum-Griffin Act (1959) is rooted to British and U.S. common law, and that this law is based upon the idea that a union is a sort of a public utility or government body. However, he avoids wrestling with the conceptual problems which are involved in direct government control of union internal affairs.

There is likewise some unbalance in the provocative contribution by Wollett, though of a different type. He devotes most of his space to explaining and defending his legislative proposals designed to make picket and boycott law more *consistent* and certain. Except as may be relevant to his proposals there is no searching analysis of the contemporary body of law governing the union conflict weapons which he treats. Further, not only is there real doubt that Wollett's proposals themselves add up to consistency, but his major premise should not be accepted without challenge. It could be argued that the capacity of our law to be inconsistent is a strength rather than a weakness. Inconsistency may be the better choice as to alternatives. Indeed, Aaron, after a sophisticated analysis of the free speech problem, rejects extreme solutions (which might result in consistency) and concludes: "the middle ground, uncertain though it may be, offers the best hope of approaching the unattainable ideal of absolute equality under the law" (p. 54).

Should not some degree of inconsistency, and even contradiction, flow from the multi-objective complex of U.S. law? It seeks at the same time to protect the employer, employee, union, and public. If the chief objective is

to assure consistency, a body of law might not have the capacity to reconcile these conflicting interests in a manner which approaches equity. In short, as worth while as consistency might be, it could be purchased at too high a price.

FRED WITNEY

L'indexation des salaires: ses répercussions économiques. By JEAN-PIERRE GERN. Neuchâtel, Switzerland: Les Éditions de la Baconnière, 1961. Pp. 198.

Gern's study is a lucid, carefully delimited analysis of the pros and cons of wage escalation, with a special focus on whether automatic, proportional adjustments to changes in cost of living tend to "unlatch" (*déclencher*) or unleash inflation. His monograph adds little to the theoretical argumentation on escalation. However, his survey of postwar experience with *l'indexation* in Italy, France, Belgium and Luxembourg should be of real value for U.S. labor economists.

Gern is concerned only with that type of *l'indexation* or *l'échelle mobile* (translated by this reviewer as wage escalation) which links wages directly to a price index (p. 19), and under "free" regimes (p. 75). An introductory and elementary analysis of the nature, purposes and technical difficulties of *l'indexation* comprises approximately the first third of the monograph. It includes a summary of attitudes toward wage escalation typically held by Western European employers, trade union leaders and various governments. The analysis embraces both social and economic factors (pp. 44-51).

To this reviewer, the most rewarding part of the study is its reasonably detailed account of experience with wage escalation in the four countries mentioned above, sprinkled with illuminating comparative references to other "free regimes," including the United States, Great Britain and Western Germany. In a concluding section, Gern comes to grips with such basic questions as whether wage escalation unleashes and prolongs inflation and whether it facilitates or hinders economic growth.

Gern claims that "direct observations" were his most important source for this study (p. 62), although admitting the inadequacy of the available data for answering some of his questions. A basic difficulty appears to have been that of separating out and identifying the impact of wage escalation per se. A comprehensive bibliographical appendix on wage escalation contains many Western European references that should be of interest and value to the U.S. labor economist.

Gern's analysis of experience with escalation in France and Italy is thorough and holds perhaps the greatest general interest. In Italy, almost all wages were subject to *l'indexation* in the postwar period. Gern found that between 1949 and 1957 wage escalation accounted for roughly half of the 56 per cent increase in the cost of Italian manual labor that occurred during the eight-year period. France offers the interesting experience of an "indexed" legal minimum wage. Gern concludes that the direct effects of *l'indexation* on the general level of wages in France do not appear to have been substantial (p. 153). As long as the increase in the legal minimum remains propor-

tional to increases in the cost of living, it is unlikely in Gern's view to have much influence on *les salaires-pilotes* or on the general level of wages.

Gern prudently acknowledges the difficulties in determining the secondary effects of wage escalation. He also is aware of the complexity of the analytical problems with which he is dealing. In commenting on the effects of partial escalation limited to industrial sectors where wages are generally the most dynamic (as in the United States), Gern shrewdly observes that escalation serves to reinforce the economic factors which operate in its absence and which "dig an always larger moat" between wages in such expanding sectors and those in tertiary industries like hospitals and hotels (p. 151).

It is Gern's opinion, based on his study of the postwar period, that the inflationary wage-price spiral is neither more violent nor more lasting with wage escalation than without it (p. 167). "The maintained rhythm and strict proportionality of the wage increase make it less dangerous because an important element of uncertainty is removed. One knows when and how the adjustment will be made" (p. 172). He concedes, however, that adjustment of wages to a previous price increase can trigger inflation in conjunction with other factors (p. 155).

HAROLD W. DAVEY

*Iowa State University of
Science and Technology*

The Employment Forecast Survey. By DOUGLAS G. HARTLE. Canadian Studies in Economics, No. 14. Toronto: University of Toronto Press, 1962. Pp. xi, 153.

Economic forecasters and students of expectations will be thoroughly discouraged by the results of this study. An evaluation of the employment forecast survey of the Canadian Department of Labour between 1952 and 1957, it finds the data to be virtually valueless for yielding reliable industry predictions of employment.

The employment forecast survey (EFS) has been in operation since 1946. In that year each of approximately 800 establishments was asked to submit every three months data on actual employment for each of the past three months as well as forecasts of its employment three and six months in the future. The purpose of these predictions was to provide a basis for anticipating future employment, specifically, the employment index of the Dominion Bureau of Statistics (DBS). These predictions were obtained by projecting the most recent DBS index by the ratio of total forecasted employment of the reporting firms at the most recent date. In practice, administrators were free to project employment on the basis of anticipated quarterly changes or on the basis of year-to-year changes, or even to adjust the data on a subjective basis to allow for special circumstances, such as a labor dispute.

The present study focuses on the predictions of manufacturing firms and, for the sake of consistency, evaluates all of the predictions on the basis of year-to-year changes. This approach removes one of the subjective elements in the analysis of the estimates and serves to increase the forecast errors only slightly.

The evaluation of the reliability of the forecasts rests upon a framework which divides the total error of a forecast into "sampling errors" and "forecast errors." This framework is based on the sampling theory concept of representing the total variance of an estimate (the mean square error) as the sum of the sampling variance and of the variance due to nonsampling errors. In this case, the sampling error is defined as the difference between the actual change in the employment of EFS-reporting firms and the change in the DBS employment index for the same period. The forecast error is the difference between the aggregate anticipated employment of the EFS-reporting firms and the actual employment for these firms. In other words, the total error is partitioned into two parts, one part measuring the extent to which the sample may be atypical of the population, and the other part measuring the extent to which the sample firms are unable to predict their own employment.

By means of this useful framework, the author is able to differentiate between the sampling errors and the nonsampling errors of the forecasts. The results are devastating:

1. The total error of the EFS forecasts, based on the three- and six-month forecasts of reporting firms (related to predicted changes from the levels in corresponding months of the preceding year), differed substantially from the actual change of employment (the DBS index). As a rule, the forecasts consistently underestimated the change in employment, being too high when employment was falling and being too low when employment was rising. Turning points were invariably missed. The three-month predictions were somewhat better than the six-month predictions but even the former were more accurate than mechanical projection of current levels barely half the time.

2. The average sampling errors were "roughly one-half of the mean changes which the sample purported to estimate" (p. 50). Like the total error, the sampling error caused the actual sample changes to deviate substantially from the changes in the DBS indexes, though the pattern of the error was somewhat different. The direction of change for individual manufacturing industries was incorrect nearly 30 per cent of the time.

3. The three-month forecast errors averaged between one-third and one-half of the actual change in employment of the sample firms, while the six-month forecast errors averaged between 50 and 75 per cent of the actual change. The direction of change was missed 20 per cent of the time by the three-month forecasts and 40 per cent of the time by the six-month forecasts, particularly damaging since the period of observation contained only one cyclical turning point. Neither the sample errors nor the forecast errors were consistent either in direction or in magnitude.

4. On an individual-firm basis, comparison of the accuracy of the forecasts against a straightforward mechanical yardstick suggests that 40 per cent of the firms in the sample submitted forecasts with no net predictive value. In many industries, the forecasts of more than half the firms were valueless by this criterion. Moreover, the direction of employment was missed by nearly two-thirds of the reporting firms at least half of the time, leading the author to conclude that, "*Under our definition of net predictive value with respect*

to the direction of non-seasonal changes we conclude that virtually none of the establishments submitted worthwhile forecasts" (page 77; italicized by the author).

The author shows that some improvement in the forecasts could have been made by removing forecasts of no net predictive value, as one would expect. However, no method could be found for carrying out this deletion in advance, particularly since firms most accurate at one time were not necessarily the firms to be most accurate at a later time.

One may quibble about various aspects of the analysis, such as its focus on a period containing only one cycle, use of arithmetic differences rather than percentage errors, and the exclusion of nonmanufacturing industries. Nevertheless, this is a highly competent piece of analysis and demonstrates conclusively that the forecasts are virtually valueless as direct predictions. In view of the substantial and erratic nature of the errors, they are also hardly likely to be of much use for indirect purposes, such as additional variables in econometric models.

Perhaps most discouraging of all is the finding that there seems to be no means of improving the forecasts. To reduce the sample error to manageable proportions, Hartle shows, would require a prohibitively large sample. Even so, since the firms in the sample (usually the larger firms in the industry) tend to be the more accurate forecasters, reduction of sampling error by increasing sample size may be achieved only at the expense of increasing forecast error, so that the net benefits may be nil. The *coup de grâce* in this respect is data showing that the sampling errors help offset to some extent the forecast errors, so that for some industries elimination of sampling errors would actually increase the total error of the predictions.

A second means of data improvement may lie in transformation of the forecasts. Hartle offers one suggestion along this line, namely, to use regression techniques to relate individual firm forecasts to the industry forecasts and to levels of over-all employment; but no evidence is submitted that the method is likely to work. Even if it were successful, the author points out that the technique is too elaborate and expensive for the resources available.

The final avenue of improvement would seem to lie in seeking improved forecasts from the individual firms. By regression analysis Hartle finds that the relative errors of the forecasts increase with the amplitude of seasonal change and with the irregularity of these changes. However, he rejects the possibility of attempting to educate firms to use better adjustment methods, in part because of presumed administrative difficulties, while seasonal adjustments by the government seem to be out of the question. Nevertheless, if such forecasts are to be improved some program of "forecast education" would seem indispensable. As has been noted in two recent studies of the employer forecasts in this country,* seasonal adjustments were generally made

* William H. Andrews and Gene S. Booker, *Forecasts of Future Labor Requirements of Indiana Employers*. Bloomington: Division of Economic Research, Indiana University, 1957; Robert Ferber, Nai-Ruenn Chen, and Fadil Zuwaylif, "Employers' Forecasts of Manpower: An Interview Study," *Journal of Business of the University of Chicago*, July 1961, pp. 387-95.

in a rudimentary way, those preparing the anticipations having little knowledge of either operating schedules of the company or of forecasting techniques. If the same is true in Canada, persuading the firm of the desirability of having these forecasts made at higher levels and with more sophisticated techniques is long overdue. In many ways such education should not be difficult, for the results could be shown to be of value not only to the government but to firm operations as well.

Other means of seeking data improvement also exist, as by using different questioning approaches. Neither this avenue nor a program of "forecast education" appears to have been tried by the Canadian government. The only change made to date, one resulting from this study, has been to prepare the forecasts by means of a diffusion index approach rather than by the ratio approach. However, this is a relatively minor change, fails to cope with the basic problem and, as Hartle notes, preliminary study suggests that the forecasts obtained by this method appear to be not much better than the ratio forecasts. Clearly, more fundamental changes are needed, or else it would seem hardly worth while spending the money to collect the data.

ROBERT FERBER

University of Illinois

The Economics of Trade Unions. By ALBERT REES. Cambridge Economic Handbooks. Chicago: University of Chicago Press, 1962. Pp. xiii, 208. \$3.50.

The latest addition to the Cambridge Economic Handbook series is a small gem, and Professor Rees is to be commended for his lucid and economical treatment of a large and complex subject. The title might have more aptly referred to U.S. trade unions, since the book is largely concerned with the experience of the United States, but the economic principles are more universal.

Rees' treatment of trade unions is at the same time sympathetic and objective. The weaknesses of some contemporary unions—e.g., restrictive practices, undemocratic procedures, occasional instances of graft or corruption—are dispassionately treated, and due weight is given to the many economic and social gains which can be credited to the trade union movement.

Those economists who like to categorize their colleagues and tilt at "Chicago School" windmills will find little here to occupy their fancies. Illustrative of Rees' balanced presentation are the following:

The view that unions make for a worse allocation of labor does not necessarily imply an unfavorable judgement of the total effect of unions. . . . an economy has other and perhaps even more important goals than the most efficient allocation of resources. [P. 94.]

The pattern of timing of price changes [by business firms] directed blame toward the unions for price rises that were often larger than the direct increases in unit labor costs . . . it has created a greatly exaggerated impression of the role of unions in an inflationary process. [P. 108.]

It is also paradoxically true that the presence of strong unions may

improve the operation of democratic processes in the general national or state government even if the internal political processes of the unions are undemocratic. [P. 182.]

The protection against the abuse of managerial authority given by seniority systems and grievance procedures seems to me to be a union accomplishment of the greatest importance. . . . In my judgement the economic losses imposed by unions are not too high a price to pay for their successful performance of this role. [P. 195.]

By proposing or supporting such measures as aid to chronically depressed areas and publicly financed medical care for the aged, unions are acting as a social conscience for the American economy. [P. 202.]

In the tradition of the Handbook series, the book is written for the beginning student. It includes only three tables and a single diagram. It would be a mistake, however, to dismiss it only as an elementary book, for the reader is led to considerable heights without being aware of the incline. In early chapters on the sources of union power and union wage policy the student learns to view the economic implications of union behavior, to observe the terms of settlement rather than just the means, and to see that in collective bargaining "economic forces are filtered through political groupings which can delay or redirect them, but not reverse their flow."

In measuring the impact of unions on earnings, Rees concludes from a variety of empirical studies that U.S. unions on the average have been able to raise relative wages 10 to 15 per cent, although losing most of this advantage during rapid inflationary periods. In periods of tight labor supply "it seems reasonable to believe that . . . there is considerable union influence on the timing of non-union wages changes and little on their amount" (p. 105). To the extent that unions do achieve a monopolistic wage advantage, the burden is borne largely by nonunion labor in the form of underemployment (i.e., an excess supply of labor in services, agriculture and other low-return occupations).

In later chapters Rees analyzes union practices affecting the rationing of jobs through control of entry, working rules and seniority systems. This section is excellently handled with a minimum of descriptive detail and without losing sight of the goal of applying economic principles to market behavior. Other textbook writers could well use this as a model.

Chapters 10 and 11 treat the union as a public institution. The absence of democratic government in many U.S. unions and the existence of corruption in some are regretted, particularly in light of the traditional union ideology, but these issues are treated with understanding. On the larger political scene Rees sees unions as a stabilizing force, giving a representative voice to workers and providing a social conscience for the nation on many aspects of current affairs.

Rees concludes that purely as an economic institution unions are probably "an obstacle to the optimum performance of our economic system." However, he adds:

Many of my fellow economists would stop at this point and conclude that unions are harmful and that their power should be curbed. I do not

agree that one can judge the value of a complex institution from so narrow a point of view. [P. 195.]

In the broader perspective, he concludes, U.S. unions have matured and have departed from their radical heritage; their membership has become stabilized and they are performing a responsible role in our society.

This reviewer has only two minor criticisms to offer. First, I would have liked to have seen a brief chapter on the process of collective bargaining to augment the excellent sections on strikes and on union wage policy. Modern bargaining theory lends itself to presentation in an introductory book when expressed nonmathematically, and can give a student clearer insight into strategy and tactics. Perhaps a second edition can round out this presentation.

Second, a brief bibliography would be an aid in guiding the reader on to further study of the problems discussed. This is not in the tradition of the Handbook series, but the footnotes are not an adequate substitute since they do not appear to give a fully representative view of the literature.

These are but small stones to cast at an unusually good book. Rees has admirably brought off a difficult task, and even the advanced student will find it both interesting and instructive reading. It would make an excellent text for an introductory course in labor economics, adequately augmented with other readings.

ALLAN M. CARTER

Washington, D.C.

Population; Welfare Programs; Consumer Economics

Family Composition and Consumption. By MARTIN H. DAVID. Contributions to Economic Analysis, No. 25. Amsterdam: North-Holland Publishing Co., 1962. Pp. viii, 110. \$2.80.

1961 Survey of Consumer Finances. Monograph No. 24. By GEORGE KATONA, CHARLES A. LININGER, JAMES N. MORGAN, AND EVA MUELLER. Ann Arbor: University of Michigan Press for Survey Research Center, Institute for Social Research, 1962. Pp. xv, 145.

The Structure of Income—Some Quantitative Essays. By IRVING B. KRAVIS. Philadelphia: University of Pennsylvania Press, 1962. Pp. v, 317.

These volumes have in common the use of sample data of household behavior and concern with demographic factors which characterize household behavior. The *Survey of Consumer Finances* is chiefly a compilation of statistics which supplement previous publications. The other two books are analytical. Professor David presents a statistical demand analysis. Professor Kravis' study covers a wide range of topics on the statistics and theory of income distribution.

Part I of the *Survey* volume summarizes the financial findings for 1961. Considerable parts of the data, such as age and income characteristics of car buyers, age of cars, number of used cars bought, age, education, and income status of instalment debt borrowers, represent the chief information available on the subject and have proven of great value to economists. Other data, par-

ticularly regarding income distribution, supplement census findings and appear to reconcile well with them. Part II consists of the quarterly surveys of consumer attitudes and inclinations to buy which have appeared previously in the press in incomplete form only. The period covered, late 1960 to 1961, was one of mild recession and slow recovery. Answers of consumers to questions on business conditions and outlook and personal experience suggest that the public was well aware of the changing business picture, and adjusted its outlook and plans in a mild pattern similar to that of business conditions.

A less mild finding was that buying plans for automobiles in October and November 1960 were up from previous years. At that time, some 15.3 per cent of families indicated plans to buy, as compared to 13.0 in 1959 (p. 92). The forecast seems to have been erroneous, since actual purchases in the fourth quarter of 1960 through the first three quarters of 1961 were down about 10 per cent from a year earlier in value and number. Automobile purchases did not increase notably until the last quarter of 1961, and this upturn was correctly anticipated by later surveys of 1961. The survey might be more useful if it were built on more analytical foundations, considering in the case of automobiles factors such as the age of car, family status, and the like, which have been found significant by G. C. Chow and others. It is to be hoped that the analytical children of the attitude surveys, such as the study by David, will come back to help the parent. Significant factors suggested by the Survey were a liking for compact cars and stable prices. The results of the attitude survey, and of other surveys modeled after it, interesting as they are, remain more questionable in value than the finance survey, as was noted in the 1955 report of the Consultant Committee organized by the Board of Governors of the Federal Reserve System to review the statistics.

More attention to the amount of error would be welcome in a summary of sample results. One test of surveys is the ability to approximate accurately global quantities such as income and financial assets known from reliable sources. Until surveys pass this test of estimation, the results will remain suspect.

David considers the effect of family size, age of head of household, family income, and marital status, on the purchases of automobiles, houses and consumer durable goods. Data were obtained from the *1955, 1956 1957 Surveys of Consumer Finances*. The attempt is not to construct general demand functions, but rather to isolate the effects of demographic factors on demand. The most common technique is a two-way classification analysis of variance, though covariance and regression extensions of the method are utilized also. For example, the average number of rooms occupied by home owners was computed for families of a given size and given income bracket (p. 59). Since the variance within classes is less than that between classes with family size or income constant, the number of rooms possessed by a family can be argued to be related significantly to family size and income. The regression findings for the case just cited suggest that the income elasticity is about one-tenth and that the effect of a one-person increase in size of family is .07 of a room, and this means that income and family size, while significant, have surprisingly small effects on demand. A further finding is that

the value of houses increases less than the size of the house with family size, so it is argued that the quality of houses bought decreases with family size, as would be expected with constant income.

In general, the results suggest that families behave rather sensibly in making the best of their income situation. For example, larger families tend to buy more producer-type durable goods, such as washing machines, than smaller families, but not to buy more furniture or television sets. Expenditure on automobiles per dollar of income declines in higher-income brackets as would be expected if the object were transportation and not prestige and glitter. Young people who presumably like to move around more, tend to spend more on cars. Home ownership increases with income above a level of about \$4000 but not below. A difficulty, which also arises in Kravis' volume, is that there is a large degree of intercorrelation of independent variables, age, income, race, etc. Experiments with composite variables such as used in factor analysis would seem to be desirable in the interest of conciseness and clarity.

A substantial part of Kravis' work is concerned with an analysis of the *Study of Consumers Expenditures, Incomes and Savings* conducted by the Bureau of Labor Statistics in 1951. It is to the author's credit that he faces the question of the accuracy of the sample as tested by its success in estimating income aggregates, wage and salaries, rent and dividends, interest, and the like. There is a serious underreporting of property-income types in the sample. Also we learn that the editing process reduced the number of usable interviews from 16,532 to 12,389 and although this gives us confidence that efforts to preserve accuracy were genuine, it also makes us nervous as to the accuracy of the results. On the other hand, there is some evidence that the inaccuracies are spread rather evenly and not biased by demographic and income factors, so that there is a good chance that the analytical results are valid.

It turns out that the various demographic factors explain in considerable degree the family income. In general, if you want to have a high income it pays to live in the north, in the suburb of a city, to be white, a salaried manager or professional employee, about 47 years of age, to have over 16 years of schooling, to live in one place for a long time, and to have a working wife. As regards race, Kravis finds that some 20-30 per cent of the differences in income can be explained by occupational bias toward low-paying occupations for the nonwhites. In the northern cities where the difference is the least, a standardized income for nonwhites is only 79 per cent of the white income (pp. 46-47). This result is very possibly not correct, as Kravis recognizes, because the occupational classification utilized in the study is too broad, but until it is corrected by further study, it certainly is alarming, not only because of what it says about racial prejudice, but because it appears to contradict the marginal productivity theory of distribution. The latter can probably be resurrected, by introducing consumer bias against nonwhite-made goods and services, or by introducing effects on the productivity of white employees, but the task would not be easy.

Theories of income distribution come into question again in the chapters

on trends in the labor share of income, and on the size distribution of income. The author finds that the labor share of income has generally tended upward, and he is confident that this is due in part to the changes in the relative supply of factors and in the nature of innovations, but beyond orienting his findings with previous discussions he does not take us far. Kravis finds income distribution to correspond more nearly to the log-normal than to any other simple distribution, but does not find this fit to be very adequate. This latter finding tends to eliminate those explanations which depend upon the assumption of the probability of a given per cent change in income. The reviewer found most convincing the argument attributed to R. H. Tuck (*An Essay on the Economic Theory of Rank*, Oxford, 1954) that income is related to the productivity which each worker gives to other workers. Assume that workers in public health, law and order, education, design, and supervision and the like require special training or talents which limit the supply, and that these employments increase the productivity of all or of a great many workers. The marginal productivity of such skilled workers will be increased much more than the size of the skill difference itself would suggest, and a skewed income distribution would result.

Many other topics are touched upon by Kravis, including international comparisons of incomes and income distribution, and trends in inequality of income in the United States. This book is an excellent starting point for any one interested in empirical results on income distribution and the relation of these to theories of income distribution.

PAUL B. SIMPSON

University of Oregon

The Development of the Social Security Act. By EDWIN E. WITTE. Madison: University of Wisconsin Press, 1962. Pp. xvi, 220. \$5.75.

Economic Security in the United States. By VALDEMAR CARLSON. New York: McGraw-Hill Book Co., 1962. Pp. xi, 225. \$6.50.

Like a number of other areas in economics, the literature on social security has traditionally been long on description but short on theory. The two books under review present strong examples of each aspect of the field. The late Professor Edwin E. Witte reviews the drafting and passage through Congress of the Social Security Act of 1935 from the vantage point of the then Executive Director of President Roosevelt's Committee on Economic Security. This committee not only was charged with formulating the Act's basic features, but it also guided the legislation through Congress. In contrast, Professor Valdemar Carlson of Antioch tries to span the gap between the applied and theoretical economics of social security by constructing a set of meaningful theoretical concepts.

The first of the two major sections in Witte's book is a legislative history of the Social Security Act, and the second is a description of how the major provisions, such as retirement and unemployment compensation, fared in the legislative process. The appendices include, among other items, the recommendation on health insurance made by the Committee on Economic Security.

Witte's book is actually a memorandum written soon after the passage of the Social Security Act but not made public until its present printing. The reason for the delay is probably that it is an "inside" story of how personalities, issues, and pressures were blended together to produce this Act. The roles of President Roosevelt, Secretary of Labor Perkins, Harry Hopkins, and various congressmen are described in detail. The debate on the 1935 Act raised alternatives to a social security system which today is accepted by many as inevitable in form. The pressures exerted by various individuals and groups, as seen in Witte's book, were strong but not as consistent as one would imagine. William Green, president of the American Federation of Labor, proposed many amendments which were interpreted as "an attack upon the bill by organized labor" (p. 87). Actually organized labor "mildly favored this measure" (p. 88). Though the National Association of Manufacturers actively opposed the bill, the president of the United States Chamber of Commerce generally supported the bill as did the National Retail Dry Goods Association. The American College of Surgeons came out for health insurance in spite of the American Medical Association's traditional opposition to it.

Witte's book is a valuable document for understanding how the Social Security Act was developed and passed. His knowledge of the political process and people was incisive. With characteristic modesty, Witte played down his own role and influence. This flaw is partly rectified in the foreword by former Secretary of Labor Frances Perkins and in the introduction by Robert Lampman of Wisconsin and Wilbur Cohen, now Assistant Secretary of the Department of Health, Education, and Welfare.

Carlson's book focuses on those "institutional arrangements which have been or are in the process of being achieved to provide income outside of wages and returns from ownership of property" (p. 1). These are nonfactor income, at least from the standpoint of the recipient. The main topics included in this short book (225 pages) are fairly traditional. The background of social insurance occupies two chapters. A chapter apiece is devoted to workmen's compensation; Old Age, Survivors, and Disability Insurance; public assistance; unemployment compensation; employee benefit programs; and supplemental unemployment benefits. Family allowances and the medical service issue are discussed separately. Preceding these topics is a discussion of the market system and following them is an analysis of economic security institutions.

Carlson's book is distinctive in its meaningful generalizations on social security institutions and theory. All too often books in this field give reams of statistics and administrative details yet miss the nub of the matter. Not so with Carlson's book, which contains no tables of figures, and includes organizational fine points only as needed to explain a concept. For example, in analyzing unemployment compensation laws, Carlson explains in detail only the concepts of availability for work and experience rating. Nevertheless, through his discussion of the issues surrounding this program, he manages to give a clear picture. Without question, this is a well-written book.

Carlson's central theme of economic security as nonfactor income runs like this: The ideology of the self-regulating market has molded the scope and character of the programs for economic security. In public assistance, rehabilitation to work-force status or provision for relief at a very minimum level are built-in principles which mesh with free market economics. In the categorical relief programs such as aid to the blind, the individual is presumed out of the labor force by consequence of his disability or other limitation. However, general relief does not gain even this limited acceptance since "sturdy vagabonds" and "valiant beggars" might be malingering and the infestation of living on governmental doles might spread to productive citizens. Social insurance programs were also molded to the free market ideal. The benefit recipient must have been attached to the productive labor force, or in the case of dependents, related to someone in the labor market. The result is that social insurance gains a more respectable standing than public assistance because the right to it has been earned through significant attachment to the free labor market. The private employee benefit programs, such as pensions and supplemental unemployment benefits, have the same respectable status as their public counterparts.

Carlson also shapes a justification for nonfactor payments through his distinction between the money expenses of production and social costs; that is, costs which develop out of industrial activity but which do not appear on the employer's account books. To Carlson, "Social insurance has proved to be a workable compromise to bridge the gap that separates the employer's interest in gearing production expenses to variable costs and the employee's interest in having his services considered as overhead cost" (p. 189).

Carlson has done a good job of revealing the impact of the free market ideology upon the shaping of economic security programs. He has performed equally well in discussing selected economic topics, such as the impact of economic security upon labor mobility, horizontal income redistribution, and worker incentives. The use of nonfactor income as an analytical tool needs, as Carlson readily admits, further development. Carlson's book should be useful as a text in social security courses and as a reference volume to economists who want to grasp the key ideas and issues in economic security.

JACK SKEELS

Wayne State University

The Economics of Public Education. By CHARLES S. BENSON. Boston: Houghton Mifflin Co., 1961. Pp. xx, 580. \$7.00.

The magnitude of public education in the United States today is unparalleled in human history. A few statistics point up this fact: In 1929, 9.8 per cent of our working force was employed in agriculture and 3.6 in educational services. In 1959, the corresponding figures were 3.7 per cent for agriculture and 5.3 per cent for education. It would be difficult, if not impossible, to find another civilization in which school teachers outnumbered its farmers. Again, over a fourth of all Americans are enrolled in schools and colleges and millions more participate in programs of adult education. All told, education

costs us \$20 billion a year and some authorities believe this figure must be doubled in a decade to meet individual and social needs. Education has become big business.

These facts demonstrate the need for exploring the economic base of public education. In the past, the practical aspects of this subject have been emphasized. Textbooks in the area have stressed such subjects as public school finance, taxation, and state and federal aid to education, all useful to legislators and public administrators as background material for carrying on their work. Analysis of such topics in operational finance as the budgeting and auditing of school funds, financial accounting for school systems, and the financial management of school property have given school administrators training in certain phases of their day-to-day tasks. The study of school finance, in fact, developed largely as a branch of school administration.

Readers well grounded in such subjects as taxation systems, fiscal policies of federal and state governments, and the budgetary process will find much that is familiar in Benson's *The Economics of Public Education*. His original contribution, implied in the title of this volume, is to broaden the scope of the subject and to shift its emphasis. What he has endeavored to do is to bring the study of the economic aspects of education into the mainstream of economic thought, and to "use economic reasoning more explicitly in dealing with school expenditures" (p. viii). In short, this is not just another how-to-do-it textbook for public officials or school executives. It offers instead a more extended treatment of theoretical subjects like demand analysis, national income measurement, the determinants of school salaries, and the effects of inflation on school expenditures than conventional texts in the area. The point of view that pervades the volume is revealed in Benson's statement that he regards marginal analysis as the "center of economic theory."

Harold C. Hunt, editor of the volume, praises Benson for his "wide competence, deep personal involvement, and distinguished background of training and teaching in the fields of economics and school finance." These qualifications are amply displayed in the breadth and scope of Benson's exposition, the range and depth of his source material, and the unusual array of valuable tables he presents on taxes, borrowings, and grants-in-aid. This book, however, has an auxiliary aim—to offer readers who lack prior knowledge of economics sufficient background to grasp Benson's ideas. The sections on elementary economics, however, tend to be theoretical in nature and they are sometimes written in lackluster style.

It is a bit early to assess the ultimate influence of this trail-blazing volume. Hunt suggests that it will result in a reappraisal of the entire area and that it will undoubtedly prove a "landmark in the literature of school finance." The burgeoning of school budgets throughout the nation and the continuing need for evaluating educational finances suggest that the first prediction will probably be realized. It may well prove a landmark in the literature of the subject as well, but it will take another decade or two before we find this out.

The Calculus of Consent: Logical Foundations of Constitutional Democracy.

By JAMES M. BUCHANAN AND GORDON TULLOCK. Ann Arbor: University of Michigan Press, 1962. Pp. x, 361. \$6.95.

In recent years, as economic theory has come to be conceived as a general theory of rational behavior, rather than merely a description of market behavior in capitalistic economies, several economists have attempted to apply the economist's theoretical techniques to the study of certain broad political and social questions that previously have been left to other disciplines. Kenneth Arrow, Duncan Black, Anthony Downs, Charles Lindblom, and Henry Oliver, for example, have helped to develop a rigorous new literature that has at once deepened political theory and broadened economic theory.

James Buchanan, a leading student of public finance, and Gordon Tullock, an imaginative political scientist, have combined their talents to produce, in the book under review, a stimulating addition to this new literature. They emphasize in their highly original treatise the relationship between constitutional procedures and economic policies. Their work is, however, distinguished from most other theorizing about political problems by its implicit ideological emphasis. The somewhat eccentric ideological quality that characterizes their writing unfortunately narrows their appeal and perhaps obscures the objective importance of some of their theories. Their right-wing view is, on the other hand, also a blessing in that it gives them an unusual perspective that must account for many of their fresh insights. In scholarship it is not perhaps necessity, but prejudice, that is the mother of invention.

Buchanan and Tullock quite plausibly argue that the utilitarian, rational type of behavior assumed in economic theory should be assumed in the study of politics as well. They go on to contend that the individual citizen's interest in constitutional provisions about the economic role of the government can be expressed essentially in terms of external economies and diseconomies. Occasionally experience under *laissez faire*, because of such externalities, may give an individual an incentive to support constitutional provisions that allow government intervention in the economy. But since in time the government will presumably act to the disadvantage of the individual he will weigh the cost of any difficulties experienced under *laissez faire* against the presumed costs or externalities that government intervention will bring.

Because of the assumed long-run disadvantages of government interventions, Buchanan and Tullock suggest that voluntary cooperation through private organizations should sometimes take the place of government action in dealing with external economies and diseconomies. Here they fall into a serious logical error. When large numbers of people are involved, there is no incentive for any one of them voluntarily to support an organization dealing with the problems posed by externalities. If a voluntary organization were formed to alleviate the problem posed by an externality, those who did not participate or pay their share of the costs would benefit as much as those who did. Accordingly no one would have an incentive voluntarily to support the

organization. Suppose a voluntary organization were formed to provide for the defense of the nation. Those citizens who did not help sustain this voluntary organization would inevitably be protected from aggression as well as those who did: everyone in the country would be protected by the external economy of the expenditure of those who supported the defense organization to protect themselves. Accordingly no one would have an incentive to support a voluntary defense establishment. It is well known that for this reason defense must be provided by a government with the power to levy taxes. Neither would an individual in a city suffering from the smoking factory chimneys of Pigou's classic example have any incentive to participate in a voluntary organization that would bribe or coerce the factory owners to eliminate the smoke problem, since no one could keep nonparticipants from enjoying the clean air that resulted from the organization's efforts.

Buchanan and Tullock confuse the reader here by giving examples of types of situations in which voluntary organizations have been formed to deal with what are (allegedly) externalities. By searching through the relevant footnotes (in the back of the book) the reader can discover that the authors define ordinary economies of scale as external diseconomies (p. 345). The potential profits that a group of firms would make if they merged or formed a voluntary organization to take advantage of the economies of large scale production are called opportunity costs which in turn are defined as external diseconomies. But this is absurd, for if any potential profit is an opportunity cost and any opportunity cost is an external diseconomy, then there are external diseconomies wherever there are unexploited profits. Voluntary or private enterprise will in time no doubt take care of any misallocations of resources that result from unexploited profit opportunities, but to define these unexploited profit opportunities as externalities, and therefore to deny that government action will be needed to cure the misallocations of resources resulting from externalities, is merely to create confusion by giving words meanings that are the opposite of those they have had in the past.

Buchanan and Tullock do however concede that some externalities need to be handled by the government. They then develop a model with which they attempt to show that a democratic government operating by majority rule will systematically tend to adopt inefficient or Pareto nonoptimal policies. They argue that a government that requires unanimous consent will on the other hand adopt only those policies that would be justified by the welfare criterion that the gainers compensate the losers, for only a policy which would leave everyone at least as well off as before would win unanimous consent. Considerations such as these in their opinion tend to explain and justify the network of checks and balances and other obstacles to majority rule in the U.S. political system. They suggest that constitutional changes, and economic policies that benefit only special groups, should be permitted only if they can muster overwhelming, if not unanimous, support.

While the authors' practical conclusions are not always novel, their theoretical contributions are distinctly original. Because of these interesting theoretical constructions, their book deserves the careful attention and criticism of economists and social scientists generally.

LEKACHMAN, R., ed. The varieties of economics—documents, examples and manifestoes. 2 vols. Cleveland: World Pub. Co., 1962. Pp. 384; 317. Paper, \$1.95 each.

"The two volumes of this book claim as their single major objective the illustration of the proposition that the economic view of life has had a rich and varied history." The seventy selections are arranged, chronologically in each case, under the following topics: Economics and Salvation; The Heroic Statesman; The Age of *Laissez-Faire*; The Economics of Utopia; Economic Reform; The Economics of Revolution; The Techniques of Economics: Theory, Measurement, History.

LIPÍŃSKI, E. De Copernic à Stanislas Leszczyński—la pensée économique et démographique en Pologne. Paris: Presses Univ. de France; Warsaw: Państwowe Wydawnictwo Naukowe, 1961. Pp. xxiii, 342. NF 18.

LLAU, P. La détermination des taux d'intérêt—étude des théories économiques contemporaines. Paris: Ed. Cujas, 1961. Pp. v, 444.

A review of interest theories from the Canonists to the present—but with the most attention given to contemporary theorists. Interest theories are classified into three categories: real, monetary, and synthetic. Among the real theories treated are those of Bohm-Bawerk and Irving Fisher, Monetary: Keynes, Joan Robinson, Hicks. Synthetic: Somers, de Villey, Modigliani, Allais, Lutz, Patinkin, Lange, Timlin, Perroux, Samuelson, and many others. The review is a critical one.

ANDREWS, R. B. Urban growth and development—a problem approach. New York: Simmons-Boardman, 1962. Pp. xi, 420. \$7.50.

"The level of interpretation in this book is directed to interested laymen, to professional people in the fields of real estate and city administration, and to upper classmen of liberal arts colleges, schools of business administration, and city planning. While the bias of the discussions is strongly economic, depth and perspective are provided by appropriate admixtures of sociology, geography, law, and political science." (From the preface.)

NOTES

EDITORIAL NOTE

Like my predecessor, Paul T. Homan, I have occupied the chair of managing editor of the *Review* for eleven years. Engrossing though the work has been and much as I shall miss it, I am certain that it is wise for the responsibility for selecting the contents of the major publication of the major economics association to be passed on fairly regularly to a younger member of the profession who will view current research afresh.

The Association is fortunate that John G. Gurley is willing to assume these responsibilities. Given his previous experience on the editorial board of the *Journal of Finance* and his recent three-months period as acting managing editor during my absence, I know that the transition will be a smooth one. His good judgment, his catholic interests in economics, his keen analytical mind, and his fine critical sense will serve the *Review* and the profession well.

He will find, as I have, that the work can only be done at all satisfactorily if he has the conscientious help of many members of the profession. A genuine concern for the advancement of economics and a strong sense of responsibility to the Association have made some of the most brilliant younger economists willing to serve on the editorial board during my eleven years—and I would have been badly off indeed without their advice and good judgment. Literally hundreds of other economists have read manuscripts for me and appraised them critically—frequently contributing substantially (but anonymously) to the research results of many, particularly younger, authors. Hundreds of economists have been willing to set aside other, more interesting work to perform the very important task of book-reviewing. To all of these people, the economics profession is heavily indebted—and so, in particular, am I. I wish it were possible for me to thank every one of them individually.

The exercise of judgment in the final selection of materials to be accorded publication is the most difficult—and sleep-disturbing—responsibility of the managing editor. No matter how much good advice may be at his disposal, he finally has to decide which of many good articles should be accepted. When space limitations permit only the acceptance of 12 to 16 per cent of the manuscripts submitted, many authors have to be disappointed. Fortunately the really important contribution nearly always is published, even though the first journal to which it is submitted may not be able to use it. And the competition for publication undoubtedly has a good effect on the quality of research in our field. Nevertheless, rejection hurts; and I want to express my appreciation to the many hundreds of authors whose papers I have been unable to accept for the almost unfailing good nature and understanding they have shown in their acceptance of my decisions—even though they did not always think them wise ones.

Finally, I must add my appreciation for the constant helpfulness, complete devotion to the task, and intelligent good judgment of my editorial assistant, Miss Doris Merriam, who after sixteen years with two managing editors of the *Review* has been unable to contemplate the prospect of breaking in still a third managing editor. I know that the many members of the Association who have known her, at least through correspondence, will join me and other officers of the Association in wishing her well in her new career with the Peace Corps in Latin America.

To John Gurley go my best wishes for a highly successful term as the fourth managing editor of the *American Economic Review*.

BERNARD F. HALEY

FELLOWSHIP AND GRANTS

The Ford Foundation is offering a limited number of fellowships in business administration, in economics, and in the social sciences for research on business, for the 1963-64

academic year. Detailed announcements about individual fellowship categories as well as nomination forms have been furnished to all institutions participating in this program. Further information may be obtained from the Ford Foundation, 477 Madison Avenue, New York 22, N.Y.

The National Science Foundation announces that the next closing date for receipt of basic research proposals in the life sciences is January 15, 1963. Proposals received prior to that date will be reviewed at the spring meetings of the Foundation's advisory panels and disposition will be made approximately four months following the closing date. Proposals received after the January 15, 1963 closing date will be reviewed following the summer closing date of May 15, 1963. Inquiries should be addressed to the Biological and Medical Sciences Division, National Science Foundation, Washington 25, D.C.

The Ford Foundation announces the sixth annual Regional Research Seminars in Economics to be held in the summer of 1963 for an eight-week period. Participation is open on a competitive basis to faculty members teaching economics or business subjects at four-year institutions of higher learning that do not offer a doctorate in economics. It is the purpose of the program to enhance the effectiveness of teaching and to encourage research studies of significance.

Fellowships provide a stipend of \$800, an additional contribution of \$200 toward living expenses, and travel expenses. Preference will be given to applicants under fifty years of age who have had at least three years of teaching experience since attending graduate school. A brochure containing the names of the seminar directors, the subject areas, and the definitions of regions will be sent to AEA members in the United States about December 1, 1962. Applications can be secured from the seminar director in the applicant's region, and must be submitted before February 1, 1963. Awards will be announced not later than March 15, 1963.

The Ford Foundation also announces the sponsorship of a summer workshop on policy problems connected with economic growth in advanced western nations, to be held June 11-28, 1963 at Carnegie Institute of Technology under the direction of G. L. Bach of the Carnegie Institute of Technology and E. F. Denison of The Brookings Institution.

The general purpose is to help young economists to undertake serious research on problems of economic growth in the United States. Participation is open on a competitive basis to economists who have demonstrated interest and competence in economic research. Preference will be given to those under forty-five years of age. Funds will be provided to cover expenses plus a modest honorarium for participants. Applications and further information may be obtained by writing to Professor Bach or Dr. Denison.

Announcements

The City University of New York (Brooklyn College, City College, Hunter College, and Queens College) has inaugurated a new doctoral program in economics. Jerome B. Cohen has been named executive officer. Visiting professors for the academic year 1962-63 are William Baumol of Princeton University and Lawrence Klein of the University of Pennsylvania.

Friends of the late Selma Fine Goldsmith are establishing a memorial fund in her name. The fund will be used to make an annual award to the outstanding graduate woman student of economics at Cornell University. Checks may be made out to the Selma Fine Goldsmith Memorial Fund and mailed to Mr. Walter G. Bruska, Director of Development, Cornell University, Ithaca, New York.

Deaths

John B. Canning, professor of economics and associate, Food Research Institute, emeritus, Stanford University, July 4, 1962.

Wilson Gee, February 1, 1961.

Reid L. McClung, former dean of the School of Commerce, University of Southern California, August 18, 1961.

Blake E. Nicholson, associate professor of business law, Wharton School, University of Pennsylvania, August 19, 1962.

John T. O'Brien, Chestnut Hill, Massachusetts, March 14, 1962.

Milton J. Schlagenhauf, Medford, Massachusetts.

Karl Scholz, professor emeritus, economics department, Wharton School, University of Pennsylvania, May 9, 1962.

L. Edwin Smart, professor of economics, Ohio State University, June 27, 1962.

C. Woody Thompson, professor and director, Bureau of Business and Economic Research, State University of Iowa, August 30, 1962.

Retirements

Alma Herbst, Ohio State University.

L. T. Morgan, University of Toronto.

Lawrence J. Nachtrab, associate professor emeritus, College of Business Administration, University of Georgia, June 1962.

Visiting Foreign Scholars

Dean B. Cameron, Australian National University: visiting professor, economics department, Wharton School, University of Pennsylvania, spring term, 1963.

J. H. Dales, University of Toronto: visiting professor, University of Chicago, 1962-63.

Miles Fleming, University of Bristol, England: visiting lecturer, economics department, Wharton School, University of Pennsylvania, 1962-63.

Herbert H. Giersch, University of Saarland: visiting professor of economics, Yale University.

John Kmenta, Sydney University, Australia: acting assistant professor of economics, Stanford University, winter and spring quarters, 1962-63.

Nissan Liviatan, Hebrew University, Israel: visiting lecturer, economics department, Wharton School, University of Pennsylvania, 1962-63.

Friedrich A. Lutz, Universität Zurich, Switzerland: visiting research professor of economics, Yale University, fall 1962.

Frank C. Spooner, University of Paris: visiting research professor of economics, Yale University.

Norman Sun, International Christian University, Mitaka, Japan: visiting professor of economics, Swarthmore College, 1962-63.

Trevor W. Swan, Australian National University: visiting research professor of economics, Yale University.

H. R. C. Wright: visiting associate professor of economics, McGill University.

Promotions

Nicholas Balabkins: associate professor of economics, Lehigh University.

Bela Balassa: associate professor of economics, Yale University.

Robert A. Battis: associate professor of economics, Trinity College.

Diran Bodenhorn: professor of economics, Ohio State University.

John G. Boyd: associate professor of economics, State University of New York.

William C. Brainard: lecturer in economics, Yale University.

Irving Brecher: professor of economics, McGill University.

Robert C. Brooks: associate professor of business administration, Vanderbilt University.

Henry W. Broude: associate professor of economics, Yale University.

Edward L. Claiborn: assistant professor of economics, United States Air Force Academy.

Clifford D. Clark: professor of economics, Graduate School of Business Administration, New York University.

John D. Colbrunn: assistant professor of economics, United States Air Force Academy.

Edwin B. Cox: associate professor of statistics, Boston University.

Ward S. Curran: assistant professor of economics, Trinity College.

Carlos F. Diaz-Alejandro: assistant professor of economics, Yale University.

I. M. Drummond: assistant professor, department of political economy, University of Toronto.

Franz Gehrels: professor of economics, Indiana University.

H. A. J. Green: associate professor, department of political economy, University of Toronto.

John Hansel, Jr.: associate professor of economics, United States Air Force Academy.

D. G. Hartle: associate professor, department of political economy, University of Toronto.

Gerald K. Helleiner: assistant professor of economics, Yale University.

John W. Hooper: associate professor of economics, Yale University.

William Iulo: associate economist, Bureau of Economics and Business Research, College of Economics and Business, Washington State University.

Douglas N. Jones: associate professor of economics, United States Air Force Academy.

Robert A. Kavesh: professor of economics and finance, Graduate School of Business Administration, New York University.

Reuben A. Kessel: associate professor of business economics, Graduate School of Business, University of Chicago.

Wade R. Kilbride: assistant professor of economics, United States Air Force Academy.

Robert E. L. Knight: associate professor of economics, University of Maryland.

A. Kruger: assistant professor, department of political economy, University of Toronto.

Sherman Krupp: associate professor of economics, Lehigh University.

K. Levitt: lecturer in economics, McGill University.

H. I. MacDonald: assistant professor, department of political economy, University of Toronto.

H. Michael Mann: assistant professor, economics department, Boston College.

Donald C. Mead: assistant professor of economics, Yale University.

Howard E. Mitchell: associate professor of economics, Western Washington State College.

E. P. Neufeld: associate professor, department of political economy, University of Toronto.

Jan Prybyla: associate professor, department of economics, Pennsylvania State University.

Henry Rosovsky: professor of economics, University of California, Berkeley.

Marvin Rozen: associate professor, department of economics, Pennsylvania State University.

Charles L. Schultze: professor of economics, University of Maryland.

Eli Schwartz: professor of finance, Lehigh University.

Jati K. Sengupta: assistant professor, department of economics, Iowa State University.

G. R. Simonson: associate professor, department of economics, Long Beach State College.

Donald R. Snodgrass: assistant professor of economics, Yale University.

Milton H. Spencer: professor of business administration, Wayne State University.

Thaddeus H. Spratlen: assistant professor of economics, Western Washington State College.

Robert W. Thomas, Jr.: assistant professor, department of economics, Iowa State University.

Jan V. Tumlr: assistant professor of economics, Yale University.

Richard A. Tybout: professor of economics, Ohio State University.

M. H. Watkins: assistant professor, department of political economy, University of Toronto.

Harold W. Watts: associate professor of economics, Yale University.

J. C. Weldon: professor of economics, McGill University.

Elmus R. Wicker: associate professor of economics, Indiana University.

W. Donald Wood: professor of economics and industrial relations, Queen's University, Ontario.

James S. Worley: associate professor of economics and business administration, Vanderbilt University.

Administrative Appointments

Robert F. Barlow: dean, Whittemore School of Business and Economics, University of New Hampshire.

August C. Bolino: branch chief, Wage and Hour Division, U.S. Department of Labor.

John Cosgrove, Georgetown University: assistant director, U.S. Office of Emergency Planning.

Howard Cutler, Pennsylvania State University: vice president for academic affairs, University of Alaska.

William J. Fellner: chairman, department of economics, Yale University.

Rendigs Fels: chairman, department of economics and business administration, Vanderbilt University.

Sherwood M. Fine, Agency for International Development: temporary assignment, director, development finance, Organization for Economic Cooperation and Development, Paris.

Robert R. France: professor of economics and associate dean, College of Arts and Sciences, University of Rochester.

Frank W. Gery: associate professor and chairman, department of economics, St. Olaf College.

Joseph E. Haring: chairman, department of economics, Occidental College.

Samuel P. Hayes, University of Michigan: president, Foreign Policy Association.

W. E. Koenker: vice president for academic affairs, University of North Dakota.

E. Russel Kuchel, University of Wyoming: dean, Bradley University.

Natalie Marshall: acting chairman, department of economics, Vassar College, second semester.

John C. Murdock: chairman, department of economics, University of Missouri.

Warren C. Robinson: acting head, department of economics, Pennsylvania State University.

Herbert I. Schiller: professor of economics and chairman, department of social studies, Pratt Institute.

George P. Shultz: dean, Graduate School of Business, University of Chicago.

J. Fred Weston: vice chairman for finance, School of Business Administration, University of California, Los Angeles.

Jeffrey G. Williamson: assistant director of the graduate program in economic development, Vanderbilt University.

H. D. Woods: chairman, social sciences group, McGill University.

John Zervas: director, Northern Greece Office, Industrial Development Corporation S.A., Salonika, Greece.

Appointments

Robert L. Able: assistant professor of economics, United States Air Force Academy.

Ljubisa S. Adamovic: assistant professor of economics, Lehigh University.

R. Albert: lecturer in economics, McGill University.

J. P. Allen: professor of economics, De Pauw University.

Clopper Almon, Jr.: assistant professor of economics, Harvard University.

Shirley Almon: instructor in economics, Wellesley College.

John J. Arena: acting instructor in economics, Yale University.

Arthur G. Auble: senior planning economist, United Nations Technical Assistance Operations, Kuala Lumpur, Malaya.

William M. Bailey: instructor in economics, University of Maryland.

F. Bairstow: lecturer in economics, McGill University.

Harry L. Barrett: professor of business administration, Boston University.

William R. Belmont, University of North Dakota: Federal Reserve Bank, Minneapolis.

George J. Benston: instructor in accounting, Graduate School of Business, University of Chicago.

Elliot J. Berg: assistant professor of economics, Harvard University.

Robert A. Berry: lecturer in economics, Yale University.

Gerald O. Bierwag: assistant professor of economics, University of Oregon.

Richard A. Bilas: assistant professor of economics, University of Southern California.

Ronald G. Bodkin: lecturer in economics, Yale University.

A. James Boness: assistant professor, Graduate School of Business, University of Pittsburgh.

Samuel Brown, Bureau of the Census: lecturer and research associate, department of economics, Georgetown University.

William J. Bruns: lecturer in economics, Yale University.

Anthony J. Bryski: associate professor of economics, Lehigh University.

Duncan R. Campbell: lecturer in economics, Yale University.

Richard E. Caves: professor of economics, Harvard University.

Raymond J. Chambers: visiting professor of accounting, Graduate School of Business, University of Chicago.

Gordon C. Church: lecturer in economics, department of economics and political science, University of Saskatchewan.

Alvin Cohen: assistant professor of economics, Lehigh University.

Donald P. Cole: instructor of economics, Upsala College.

Robert E. Coleberd, Jr.: assistant professor of economics and business, Bridgewater College.

Robert L. Crouch: visiting assistant professor, Northwestern University.

George Dalton, Bard College: visiting associate professor, Northwestern University, beginning January 1963.

Jim E. Davis: assistant professor, department of economics, Long Beach State College.

Phoebus J. Dhrymes: assistant professor of economics, Harvard University.

E. Keith Dix: instructor in economics, University of Maryland.

F. Trenery Dolbear, Jr.: acting instructor in economics, Yale University.

John Douglas: assistant professor of commerce, University of Kentucky.

David F. Drake: instructor in accounting, Graduate School of Business, University of Chicago.

Emmanuel M. Drandakis: lecturer in economics, Yale University.

S. Erik Drugge: instructor in economics, Ohio State University.

Doris M. Drury: instructor in economics, University of Wyoming.

Christopher W. Dungan: instructor in business administration, Vanderbilt University.

Loretta M. Dunphy: associate professor of economics, Incarnate Word College.

Henry C. Durham, University of Munich, Germany: lecturer in economics, University of Maryland.

John W. Eilert: assistant professor of economics, St. Olaf College.

Douglas H. Eldridge: Lincoln professor of public finance, Claremont Men's College.

Stanley L. Engerman: assistant professor of economics, Yale University.

Michael J. Farrell: visiting professor of economics, Yale University, fall term.

J. Kaye Faulkner: instructor in economics, Western Washington State College.

John C. H. Fei: associate professor of economics, Yale University.

Eberhard M. Fels: professor of statistics, social sciences and mathematics, Graduate School of Business, University of Pittsburgh.

Albert A. Fitzpatrick: assistant professor of economics, United States Air Force Academy.

James W. Friedman: acting instructor in economics, Yale University.

Joseph C. Furey: instructor in economics, University of Maryland.

John Galbraith: lecturer in economics, McGill University.

Sigfried Garbuny: lecturer, department of economics, Georgetown University.

Martin A. Garrett, Jr.: instructor in economics and business administration, Vanderbilt University.

C. W. Gonick: instructor, department of economics and political science, University of Saskatchewan.

Paul Green: associate professor of marketing, Wharton School, University of Pennsylvania.

William F. Hahn: member of the professional economic staff, Bureau of Labor Statistics, Division of Wages and Industrial Relations.

Sajjad A. Hashmi: lecturer in economics, Ohio State University.

Robert H. Haveman: instructor in economics, Grinnell College.

Benjamin Higgins: visiting professor of economics, University of California, Berkeley, spring term 1963.

Robbin R. Hough: assistant professor of economics, department of business-economics, Michigan State University Oakland.

Shane J. Hunt: lecturer in economics, Yale University.

Bennett Hymer: University of Wisconsin, Milwaukee.

Stephen H. Hymer: assistant professor of economics, Yale University.

John F. Kain: instructor in economics, United States Air Force Academy.

Richard J. Kalish: instructor in economics, Lehigh University.

Nake M. Kamrany: lecturer in economics, University of Southern California.

Marshall Kaplan, Council of Economic Advisers: professorial-lecturer and research associate, department of economics, Georgetown University.

Hirschel Kasper: instructor, department of economics, Iowa State University.

Robert Katz: lecturer, department of economics, Georgetown University.

James R. Kenall, U.S. Department of Agriculture: instructor, department of agricultural economics, Ohio State University.

Shinkyung Kim: instructor in economics, University of Pittsburgh.

Sidney Klein: adjunct associate professor of economics, Columbia University, spring term, 1962-63.

Iwan S. Korocheck: assistant professor of economics, Notre Dame University.

Philip S. Kronenberg: instructor in economics, San Antonio College.

Ernst Kuhn, University of Wyoming: economist, Federal Reserve Bank, Chicago.

Eugenio F. Lari: instructor in economics, Vanderbilt University.

George E. Lent, Dartmouth College: chief, Fiscal Mission to Ecuador, Organization of American States.

Lawrence A. Leonard: associate professor of economics, Lehigh University.

William R. Leonard: deputy commissioner for technical assistance, United Nations, New York.

Harvey J. Levin: professor, Hofstra College.

Marvin T. Levine: assistant professor of economics, Ohio State University.

Arthur W. Lewis, University of the West Indies: professor of economics and international affairs, Princeton University.

N. Paul Loomba: associate professor of economics, Lehigh University.

David Loschky: assistant professor, economics department, Boston College.

Joseph Lowenberg: lecturer, department of economics, Georgetown University.

John Lowry, Graduate School of Business, University of Pittsburgh: assistant professor, University of Santa Clara.

Jacob Marschak: professor, department of economics, University of California, Los Angeles.

Joseph P. Meck: instructor in economics, University of Maryland.

Bagdan Mieczkowski: assistant professor, economics department, Boston College.

Peter Mieczkowski: lecturer in economics, Yale University.

Robert Mundell: lecturer, department of economics, Georgetown University.

J. Carter Murphy: professor of economics, Southern Methodist University.

John F. Muth: visiting lecturer in economics, Yale University.

Wladimir Naleszkiewicz: assistant professor, department of economics, Marquette University.

R. Newsom: lecturer in economics, McGill University.

Boyd Z. Palmer: operations research analyst, Atlas Chemical Industries, Wilmington, Delaware.

William N. Parker: professor of economics, Yale University.

Laurel E. Pease: instructor in economics, Denison University.

Merton J. Peck: professor of economics, Yale University.

John Peterson, associate director, Industrial Research and Extension Center, University of Arkansas: professor of economics, College of Business Administration, University of Arkansas.

Kirk R. Petshek, Mayor's Office, Philadelphia: professor of commerce and coordinator of urban research-action program in Milwaukee, University of Wisconsin.

Warren A. Pillsbury: instructor in economics, Lehigh University.

Richard C. Porter: assistant professor of economics, Yale University.

Clark R. Puckett, Federal Reserve Bank of San Francisco: assistant professor, department of economics, Long Beach State College.

Clair J. Reilly: instructor in economics, Lehigh University.

Clark W. Reynolds: lecturer in economics, Yale University.

Leigh C. Rhett: lecturer in economics, Lehigh University.

John S. Rice: lecturer in geography and industry, Wharton School, University of Pennsylvania.

John W. Rowe, Jr.: instructor, department of economics, Iowa State University.

Terence Russell: lecturer in economics, McGill University.

Richard Skinner: instructor, department of agricultural economics, Ohio State University.

Robert L. Slighton, Stanford University: economics department, RAND Corporation.

Ronald Soligo: acting instructor in economics, Yale University.

Curtis H. Stanley: assistant professor of economics, Yale University.

Ian A. Stewart, Cornell University: instructor in economics, Dartmouth College.

Donald C. Streever: director of economic research, National Analysts, Inc., Philadelphia.

Herbert E. Striner, Stanford Research Institute, Washington Office: director of program development, W. E. Upjohn Institute for Employment Research, Washington, D.C.

Adolf Sturmthal, University of Illinois: visiting professor of economics, Yale University.

John R. Summerfield, RAND Corporation: corporate staff economist, Corporate Planning and Control, Douglas Aircraft Company.

Proctor Thomson: Lincoln professor of economics and administration, Claremont Men's College.

Richard S. Thorn: economic consultant, Committee of Nine, Alliance for Progress, Washington, D.C.

Brian R. Van Arkadie: lecturer in economics, Yale University.

Paul L. van Moeseke: assistant professor, department of economics, Iowa State University.

Haskell P. Wald, Federal Reserve Bank of New York: associate director, Office of Tax Analysis, U.S. Treasury Department.

Irvin Weintraub: instructor in economics, University of Maryland.

Donald Wellington: instructor in economics, University of Wyoming.

James R. Williams: assistant professor of economics, Syracuse University.

C. Z. Wilson, Jr.: De Paul University: associate professor of business enterprise, State University of New York, Harpur College.

Thomas A. Wilson: assistant professor of economics, Harvard University.

J. W. L. Winder: assistant professor of economics, department of political economy, University of Toronto.

Donald L. Winkelman: instructor, department of economics, Iowa State University.

Francis O. Woodard: assistant professor of economics, Ohio State University.

Hsiu-Kwang Wu: assistant professor of business administration, Boston University.

Menahem E. Yaari: assistant professor of economics, Yale University.

Leaves for Special Appointments

Gardner Ackley, University of Michigan: President's Council of Economic Advisers, for two years.

Reynold E. Carlson, Vanderbilt University: Ford Foundation representative in South America, 1961-62.

William Iulo, Washington State University: economist, Office of Economics, Federal Power Commission, Washington, D.C.

Frank L. Keller, Tulane University: director, Natural Resources Division, Latin American Institute for Development Planning at Santiago, Chile, under the United Nations Technical Assistance Programme, 1962-63.

Walter Krause, State University of Iowa: visiting professor of economics, University of California, Riverside, 1962-63.

Francis Kutish, Iowa State University: Ministry of Agriculture, Columbia, July and August.

Samuel H. Newlove, University of Chicago: visiting professor of business economics and policy, School of Business Administration, University of California, Los Angeles, 1962-63.

Alvan J. Obelsky, University of Michigan, Dearborn Center: Fulbright lecturer in international economics, Kobe University, Japan, 1962-63.

Arnold A. Paulsen, Iowa State University: visiting professor, Institutionen for Rantbrukets Driftsekonomi, Uppsala, Sweden, September 1962-February 1963.

William G. Phillips, Assumption University, Windsor, Ontario: visiting professor, department of political economy, University of Toronto.

Andre Raynauld, University of Montreal: visiting professor, department of political economy, University of Toronto, spring term, 1962-63.

Robert M. Reeser, Ohio State University: Ohio State Contract Team in India for two years.

Raymond Richmond, University of Pittsburgh: Pan American Union in Panama and Colombia.

Resignations

George Bickel, Lehigh University.

Gerard Brown, Georgetown University.

Robert J. Corkhill, Lehigh University.

Donald W. Hill, Lehigh University.

Robert H. Johnson, State University of Iowa.

Monroe Newman, head, department of economics, Pennsylvania State University.

S. Ostry, McGill University.

Ben J. Pedrotti, Lehigh University.

Ryuzo Sato, University of Washington.

Jacob Stockfisch, School of Business Administration, University of California, Los Angeles.

Barry E. Supple, McGill University.

Miscellaneous

Alice Bourneuf, appointed book review editor for the *Review of Social Economy*.

Charles L. Schultze, University of Maryland, appointed assistant director, Bureau of the Budget for Fiscal Policy, Executive Office of the President.

VACANCIES AND APPLICATIONS

The Association is glad to render service to applicants who wish to make known their availability for positions in the field of economics and to administrative officers of colleges and universities and to others who are seeking to fill vacancies.

The officers of the Association take no responsibility for making a selection among the applicants or following up the results. The Secretary's Office will merely afford a central point for clearing inquiries; and the *Review* will publish in this section brief description of vacancies announced and of applications submitted (with necessary editorial changes). Since the Association has no other way of knowing whether or not this section is performing a real service, the Secretary would appreciate receiving notification of appointments made as a result of these announcements. It is optional with those submitting such announcements to publish name and address or to use a key number. Deadlines for the four issues of the *Review* are February 1, May 1, August 1, and November 1.

Communications should be addressed to: The Secretary, American Economic Association, Northwestern University, Evanston, Illinois.

Vacancies

Labor economists: Department of Labor has openings for work in the fields of wages, manpower, employment, labor and industrial labor conditions and related fields. Salaries range from \$6,435 to \$13,730 depending upon experience and training. To apply, send résumé or Standard Form 57 to the Executive Secretary, Board of U.S. Civil Service Examiners, U.S. Department of Labor, Washington 25, D.C.

Industrial organization, trade regulation, industrial concentration, structure of industry, price behavior: The Antitrust Division of the U.S. Department of Justice has openings for economists in Washington, D.C. Candidates should possess a background of education or experience in above fields. Duties involve the application of economic analysis to the enforcement of the antitrust laws. All positions are within the competitive civil service; entrance salaries range from \$5,540 to \$11,150 per annum. Write: Mr. John W. Adler, Chief, Personnel Office, Department of Justice, Washington 25, D.C.

Economics: University teaching appointment in Latin America. Prerequisites: graduate of an accredited college with major in economics and emphasis in the labor field; experience in industry or trade union desirable; prefer applicant working toward advanced degree; native fluency in Spanish; amenable in social situations. Job description: two-year contract on staff of economics department in Latin-American university. Starting salary, \$7,500 to \$8,500, plus allowances, depending upon qualifications. Send résumé. P258

Regional economics: Ph.D. or M.S. plus four years of research experience. Conduct fundamental and applied research on interdisciplinary problems in fields of regional development and long-range planning. Research on domestic and foreign areas using team approach. Send résumé of education and experience in research to L. G. Hill, Battelle Memorial Institute, 505 King Avenue, Columbus 1, Ohio.

Economics: Applications are invited for a Lectureship or Senior Lectureship in Economics at the University of New England, Australia. Post involves undergraduate teaching in economic theory and/or money and banking, and research in fields of appointee's own interest. The normal teaching load is about four class hours per week. The Department is of moderate size, at present 12 faculty members. Salary scale for Senior Lecturer: £A2,597 by £A95 to £A3,047; for Lecturer: £A1,777 by £A105 to £A2,482. Status and initial salary according to qualifications and experience. Fare to Australia paid for appointee, wife, and children, plus a baggage allowance. Appointment may be permanent or for three years. In the latter case, £A400 will be paid toward return fares. Further information obtainable from Professor of Economics, University of New England, Armidale, N.S.W., Australia.

Transportation economist: Co-operative federal-state-local agency working on comprehensive transportation plans for upstate New York metropolitan areas is seeking an economist to work on its interdisciplinary research and planning team. Examples of work are forecasting regional economic growth and studying investment in transportation networks. Beginning salary \$9,450. Full data processing, computer, and publication facilities. Send résumé, including present salary, to Roger L. Creighton, Director, Niagara Frontier Transportation Study, 79 North Pearl Street, Albany, New York.

Business administration: Position to begin September, 1963. Person whose teaching areas would be first-year accounting, management, marketing, finance, and to supervise business seminar in a small liberal arts college. Ph.D. or most requirements completed. Salary dependent upon education and experience. Apply to: Dean David A. Waas, Otterbein College, Westerville, Ohio.

Economics: Position to begin September, 1963. Person to teach principles of economics and several advanced economics courses in a small liberal arts college. Ph.D. or most requirements completed. Salary dependent upon education and experience. Apply to: Dean David A. Waas, Otterbein College, Westerville, Ohio.

Economist: With training and/or experience in regional economic analysis and development. Some knowledge of Canada's Maritime economy desirable but not necessary. Salary to \$8,000, depending on qualifications. Apply to: Director, Extension Department, St. Francis Xavier University, Antigonish, Nova Scotia, Canada.

Statistics and economics: The Internal Revenue Service in Washington, D.C., has a limited number of openings for qualified econometricians to assist in preparing studies for the Treasury Department's tax legislation program. The agency also needs statisticians with economics and economists with statistics. There are also several openings for mathematical and analytical statisticians. Civil Service requirements apply. Starting salaries range from \$7,560 to \$13,730 per annum, depending upon qualifications. To apply, send complete résumé or Standard Form 57 to Mr. Carl A. Castelda, Chief, Employment Section, Personnel Division, National Office Branch, Room 1109, Internal Revenue Service, Washington 25, D.C.

Accounting: Teacher for a small collegiate school of business in a metropolitan area in New England, starting fall of 1963. Prefer applicants with Ph.D. or substantial completion of work toward Ph.D. Full-time position in Accounting Department; no previous teaching experience necessary; rank and salary open; 9-month school year. P261

Economists: Four new openings in a rapidly growing state university in Midwest. Can be filled at any rank in almost any field of specialization. All positions require a Ph.D. in economics. Senior positions also require teaching experience, research ability, and publications. Experience directing doctoral dissertations regarded as especially valuable. One position available in February, 1963; three positions available in September, 1963. Salary (\$7,500 to \$15,000) and rank dependent upon qualifications. Write to James R. Elliott, Acting Head, Department of Economics, Northern Illinois University, De Kalb, Illinois.

Research economist: A major West Coast integrated oil company, with headquarters in Los Angeles, requires Ph.D. (or all work completed except dissertation) to develop major economic analyses and evaluate studies made by others and to predict long-range trends and short-run fluctuations in the general economy with emphasis on the western states. Experience, preferably in the petroleum field, is highly desirable but not required. The minimum annual salary for an inexperienced candidate will be \$9,000. However, the actual salary will be based on the applicant's qualifications and experience and will be supplemented by an outstanding employee benefit program. Application, with complete details and personal résumé, will be treated with strict confidence. P262

Research economist, water resources: Office of Saline Water, U.S. Department of Interior, has opening in Washington, D.C., for research economist with background in natural resources, economic geography, or utilities. Master's degree in economics is required. To assist in the administration of a challenging economic research program through contracts and grants, concerned with comparative water costs and nationwide prospects of saline water conversion. Salary range: GS-11 (\$7,560) to GS-14 (\$12,210), subject to increases under pending legislation. Send résumé or Standard Form 57 (Application for Federal Employment) to Director, Office of Saline Water, U.S. Department of the Interior, Washington 25, D.C.

International economics: Major U.S. corporation with extensive overseas operations has openings for economic analysts. Positions are in Economics Department of International Staff. Responsibilities include preparation of reports and recommendations on economic developments likely to affect foreign operations in various countries. Areas of concentration include (1) investigation and projection of foreign economies, (2) private international capital and credit transactions, (3) exchange rates. Candidate should have M.A. degree at a minimum; preferred applicants will have completed all Ph.D. requirements, except thesis. Research and teaching experience helpful. Initial salary will be commensurate with qualifications. Age limits, 25 to 45. Covering letter should accompany résumé. P263

Business administration and economics: Robert College, in Istanbul, Turkey, presents a challenge in education. An opportunity to contribute significantly to the development of a young republic is available to specialists. Graduate degrees required. Address inquiries to Miss Shirley Osmun, Personnel Officer, Robert College, Bebek Post Box 8, Istanbul, Turkey, with copy to the Near East College Association, 548 Fifth Avenue, New York 36, New York.

Statistician: The International Labor Office in Geneva, Switzerland, invites applications for a statistician to assume responsibility for the statistical aspects of manpower assessment problems, with particular emphasis on manpower in developing countries and labor requirements for economic development programs. Fuller information may be obtained by requesting Notice of Vacancy No. 721 from the Washington Branch, International Labor Office, 917 15th Street, Washington 5, D.C.

Economists: Stanford Research Institute has opportunities for economists to conduct research for development agencies of the United States and foreign governments, as well as foundations and private organizations. The studies will be concerned with development of industry, natural resources, and human resources; assistance in development programming and the building of development institutions; urban, regional, and national growth problems; application of science and technology in the developing nations; international economic relations. There are opportunities for rotation of staff assignments between international and domestic projects. The working atmosphere is academically oriented with industrial level salaries and benefits. Interested applicants should submit résumé to C. R. Wherry, Stanford Research Institute, 333 Ravenswood, Menlo Park, California.

Economist: A new position involving undergraduate-graduate instruction in a former teacher training institution which is initiating a liberal arts program (undergraduate enrollment 4,000; graduate, part-time, 2,000). Twelve-hour load teaching principles and problems courses plus electives. No negative restrictions as to race and sex. Hope to fill the position at associate professor rank. Preferably Ph.D. or at least 70 hours of graduate work. Five years of teaching or equivalent required. A dramatic salary revision possible, depending on action of the state legislature after January 1, 1963. Nine weeks of summer teaching are available. Present scales are: two semesters, \$5,500-\$7,500; summer, \$1,620. Apply to Dr. Raymond L. Lee, Social Science Department, State College, Indiana, Pennsylvania.

Economics: Principles and one advanced course, eastern Catholic men's college, beginning September, 1963. Should have doctorate or all work completed except dissertation. Instructor, \$5,400-\$6,600; assistant professor, \$6,400-\$7,600. Retirement program in addition to social security; sabbatical leave program. Rank and salary according to education and experience. Man ready for associate professor level also considered. P264

Senior economist: Economics division of New York research institution has opening for senior economist. Ph.D. in economics and experience in economic research. Combined research and teaching background desirable. Familiarity with national income accounts and application of economic theory to analysis of current developments; writing experience and skill essential. Starting salary to \$18,000, depending on qualifications. Liberal pension and other benefits. P265

AMERICAN ECONOMIC ASSOCIATION

Northwestern University, 629 Noyes Street, Evanston, Illinois

This deceptively simple equation is the real reason why you enjoy the best and the most telephone service in the world at the lowest possible price.

It represents the relationship between three basic units that equal one unified Bell System.

1. Patient research and development by Bell Telephone Laboratories create constantly improved communications techniques. (Telstar is one recent example.)
2. Efficient manufacture by Western Electric delivers equipment you can depend on, day after day, year after year.
3. Skillful operation by 21 Bell Telephone Companies supplies service at a high standard of performance to families and farms, to industry and government.

The work of these units is closely coordinated by the American Telephone and Telegraph Company, advising and planning for the progress and efficiency of the entire system.

That's why we say, "Three equals one"—and why you can pick up your own telephone at home and talk to almost anyone else in all 50 states of the union or any of 167 foreign countries around the world—quickly and economically.

NEW

Books of Vital Interest

☐ INCOME AND WELFARE IN THE UNITED STATES

By JAMES N. MORGAN, HARVEY E. BRAZER, WILBUR J. COHEN, *all of the University of Michigan*; and MARTIN H. DAVID, *The University of Wisconsin*. 544 pages, \$7.95.

A national personal-interview survey is employed to study the distribution and redistribution of income, what determines peoples' incomes, and the intergenerational transmission pattern. The analysis of this survey combines demographic, economic, and social-psychological measurements on each family studied to give a detailed explanation of what determines the economic position of that family.

☐ ECONOMIC SECURITY IN THE UNITED STATES

By VALDEMAR CARLSON, *Antioch College*. Economics Handbook Series. 240 pages. \$6.50.

This challenging text asks the reader to study the subject of economic security objectively. It is a venture in institutional economics, written to provide a synthesis or a perspective on economic security. The book maintains that the scope and character of economic security in the United States is determined by the imperatives of the market system. Each of the programs of economic security is covered in the context of a functioning economy. The text helps the reader gain an overall understanding of each of the programs of economic security, including private pension plans and welfare programs, by subordinating details of individual acts in favor of historical developments and theoretical interpretations.

☐ THE FIRM: Microeconomic Planning and Action

By NEIL W. CHAMBERLAIN, *Yale University*. 448 pages, \$7.95.

This text provides a framework within which economic theory of the firm can

be meaningfully set, and within which business policies can most fruitfully be analyzed. It portrays the planning function (with its emphasis on organization, fund flows through time, and relating the organization to its environment) as a profitable meeting ground for the scholar and practitioner. Underscores the importance of the planning function to the firm and the economy.

☐ INTRODUCTION TO LABOR ECONOMICS, Third Edition

By ORME W. PHELPS, *Claremont Men's College*. 566 pages, \$7.50.

Describes the principal forces at work in the U.S. labor market (employer, employees, unions, and government agencies) and the issues raised by their interaction. Over half the book deals with labor unions: their history, organization, methods, legal status, and objectives. The remainder of the text discusses and analyzes the general character of the labor force and the labor market, the economics of wages, and the modern theory of employment.

☐ INTERNATIONAL ECONOMIC INSTABILITY

By JOSEPH D. COPPOCK, *Earlham College*; currently Director, Foreign Economics Advisory Staff, Office of the Under Secretary, U.S. Department of State, Washington, D.C. Economics Handbook Series. 192 pages, \$7.95.

Describes and explains international economic instability, emphasizing the years since World War II with a view to evaluating and devising measures for reducing such instability when it serves no useful purpose. The basic approach is empirical, stressing policy considerations. Contains highly original material in chapters three and four, including some new and interesting factual conclusions about international economic instability during the postwar years. The country approach is stressed, since countries are the primary organizational units for dealing with the problem.

UPCOMING to the Economist

□ SECURITY ANALYSIS: Principles and Technique, Fourth Edition

By B. GRAHAM, *The University of California, Los Angeles*; D. L. DODD, *Columbia University*; S. COTTLE, *Stanford Research Institute*. 800 pages, Textbook Edition \$9.95.

An excellent book, comprehensively updated. Devoted to the pragmatic aspects of security analysis and security selection in context of professional investment management. Gets down to the basics of selecting and rejecting securities for investment purposes, and endeavors to show readers how to go about it. Substantial revision permits book to take a position on all major problems that exist today in the analysis and appraisal of common stocks. A very valuable book for anyone interested in the investment of securities.

□ ECONOMICS, Principles, Problems, and Policies, Second Edition

By CAMPBELL R. McCONNELL, *University of Nebraska*. Available in March, 1963.

A thoroughly up-dated and expanded revision of a widely-acclaimed introductory economics textbook. As in the first edition, the basic purpose is a clear and definitive presentation of the principles of economics. The author has used the *economizing problem*—the dilemma of scarce resources and unlimited wants—as the unifying principle or theme for the many diverse topics discussed in the text. The treatment is rigorous. Difficult subject matter is not omitted or de-emphasized, but rather is given more extended treatment verbally, numerically, and graphically. One of the most distinguishing features of the book is the author's thorough treatment of microeconomics. Text can be used for either a one semester or two semester course.

□ THE FINANCIAL HISTORY OF THE UNITED STATES, Second Edition

By PAUL STUDENSKI and HERMAN E. KROOSS, *New York University*. Available in January, 1963.

This completely up-dated revision describes, analyzes, and interprets what has happened to the history of government financial activity and policy: government expenditures, revenues, debt operations, debt management, and money and banking. History and theory have been interwoven throughout to give the reader an understanding of how and why fiscal and monetary policies have evolved from their very simple beginnings in the Colonial period to the complicated system of the 1960's. Text can be used at either the undergraduate or graduate level. It covers all the ramifications of the interrelationship between the government and the money supply, with careful attention to the whole existing body of fiscal and monetary theory. It includes the most exhaustive set of statistics on Federal finance available anywhere.

□ ECONOMETRIC METHODS

By J. JOHNSTON, *The University of Manchester, Manchester, England*. Available in January, 1963.

Up-to-date text provides a new approach toward teaching econometrics. Starting with the assumption that most students will have had a year of statistical theory and method, book begins at this level and builds an integrated and self-contained development up to and including the latest theoretical developments. Part I contains a full exposition of the linear normal regression model and Part II expounds the main statistical methods now available for the estimation of econometric models. Matrix algebra is used for exposition and book includes chapter covering all elements of matrix algebra required. Numerical examples illustrate text and a selection of problems is given at the end of each chapter.

INTERNATIONAL TRADE *and* DEVELOPMENT

Gerald M. Meier

This clear and concise book sets forth the fundamental principles of the international economics of development and considers the main topics in the pure theory and monetary theory of international trade from the standpoint of international development. Traditional trade theory is shown to offer a powerful set of fundamental principles for illuminating development problems of underdeveloped countries. Discussions are analytically coherent; central issues are clarified; the major insights are consolidated. 209 pp. \$4.25.

PRICING POWER and the PUBLIC INTEREST

A Study Based on Steel

Gardiner C. Means

The co-author of *The Modern Corporation and Private Property* here presents a new concept for bringing prices into line with the public interest. "Means combines in striking and original fashion a number of institutions into a suggested pattern of industrial self government. . . . An outstanding achievement. . . . The book is more than thought provoking; it is an outstanding contribution and ahead of its time." *American Economic Review* "A new book by Gardiner Means is bound to be an event. . . . His suggestions are creative and should receive prolonged study and critical discussion. . . . Means is to be congratulated on his courage as well as on his insight." Kenneth E. Boulding \$7.50

New in '62 . . .

STATISTICAL MANAGEMENT OF INVENTORY SYSTEMS

(Publications in Operations Research No. 6)

By HARVEY M. WAGNER, *Stanford University; Consultant to McKinsey and Co. Inc., the RAND Corporation, and Service Bureau Corporation.* Emphasizing and exploring the fundamental difficulties in the implementing of Operations Research policies, this book focuses on the designing of consistent sets of control schemes and provides the necessary tools for analyzing inventory control devices. Stress is placed on the control of personnel as well as on the fashioning of inventory procedures. 1962. 235 pages. \$8.95.

PRICE, OUTPUT, AND INVENTORY POLICY

**A Study in the Economics of the Firm and Industry
(Publications in Operations Research No. 7)**

By EDWIN S. MILLS, *The Johns Hopkins University.* The author formulates, analyzes, estimates and tests models of firms' decision making and emphasizes careful integration of theoretical and empirical studies. Interdisciplinary in nature the book draws on work in economics as well as in operations research and management. 1962. 271 pages. \$7.95.

LABOR LAW

By NICHOLAS S. FALCONE, *Fordham University.* A chronological presentation of labor law beginning with 1349 in England and continuing with contemporary experiences flowing from the enactment of the 1959 Landrum-Griffin Act, this book is divided into two parts: one dealing with the evolution of the labor law in England, and the second covering the complete development of labor law in the United States. 1962. 502 pages. \$7.95.

ESSAYS ON PROBABILITY & STATISTICS

By M. S. BARTLETT, *University College, London.* A consistent and comprehensive view of statistical theory is represented by these papers delivered over a long period by the author. This collection is an elementary, but relevant commentary on the controversial problem of statistical inference. 1962. 127 pages. \$4.50.

Send for examination copies.

TEXTS FROM APPLETON-CENTURY-CROFTS

RISK AND INSURANCE

by James L. Athearn, University of Florida

Written in clear, nontechnical language, this recent text applies the modern concept of risk to teaching the principles of insurance.

526 pages, illustrated, \$6.95

"In using the approach of risk management, Professor Athearn has written one of the best introductory texts available for a one-semester course." Edmund E. Smith, University of Portland, Oregon, College of Business Administration.

ELEMENTS OF MODERN STATISTICS

by Boyd L. Nelson, University of Maryland

This recent book, written for courses in elementary business and economics statistics, provides students with sufficient knowledge to apply statistics in their fields, to understand their power and usefulness, and to realize their limitations.

366 pages, illustrated, \$6.00

"An unusually good elementary text. It is well-organized and has a good elementary treatment of statistical theory without an excess of descriptive materials." Roger L. Burford, Georgia State College of Business Administration.

CAPITALIST AND SOCIALIST ECONOMIES

A Marxist Analysis of Modern Political Economy

By ROBERT BRUCE DRISCOLL

Marxian economics (as extended by Driscoll) scientifically relates value, price, productivity, credit, and inflation:

$$(P'/V)_0 = (P'/u) \times (u/V);$$

(Price of value of a commodity) = (Price) \times (Productivity). P' is monetary price; V is value in average labor time of production; u is a given use value such as an automobile, a pair of shoes, a lathe, etc.

Aggregate price of value is the aggregate price of the aggregate value of all commodities sold to final users during an accounting period.

$$(P'/V)_t = (P'/V)_0 [1 - C''/(G' + L' + M')]^{-t} = (P'/V)_0 \times (IF);$$

aggregate price of value at time t is equal to aggregate price of value at earlier time $t = 0$, multiplied by the *inflationary factor* (IF): unity divided by unity less the ratio of net aggregate extension of credit by finance capital divided by the aggregate price of all commodities (gold, labor power, goods and services) sold to final consumers in the period $0 - t$.

Inflation is primarily of the price of value; only secondarily is price affected, and then only in conjunction with the effects of productivity.

$$CIF_n = IF_1 \times IF_2 \times IF_3 \dots IF_n;$$

the cumulative inflationary factor for a series of n successive accounting periods is the cumulative product of the inflationary factors for each period.

$$(P'/V)_n = (P'/V)_0 (CIF_n).$$

The above relationships are confirmed by overall U.S. economic data for the period 1935-1960.

101 pp. (8½ \times 11) including 6 pp. national economic data, 8 figures, table of contents, index, political footnotes. Mimeographed, elite type, 24 lb. white paper, stapled and masked. Postpaid. Soft cover \$1.00. Hard cover \$2.00.

ECONOMICS**

THE NATURE OF PRICE THEORY

By H. H. LIEBHAFSKY, *Professor of Economics,
University of Texas*

This new up to date book contains a clear, precise presentation of basic concepts and relationships incorporated in a more completely integrated and comprehensive coverage than is found in any other price theory textbook on the market. Basic concepts are illustrated in four different ways: (1) verbally, (2) continuing simple algebraic formulations, (3) arithmetical illustrations based on the algebraic formulations, and (4) graphs based on the arithmetical illustrations. To comprehend the material, the student need only have a basic knowledge of elementary algebra. *Ready in January.*

Also Consider:

ECONOMICS: Principles and Issues

By Delbert A. Snider, *Miami University*

This basic text for introductory courses explains economic principles and theory in a way that is most revealing and meaningful for contemporary economic problems and issues. An accompanying *Workbook* by Wallace I. Edwards is available.

LABOR ECONOMICS

By Chester A. Morgan, *State University of Iowa*

In this basic text for courses in labor economics or labor problems, the material is organized in a connected, continuous, and concise presentation which is characterized by a continuity not generally found in the usual approach.

ECONOMIES OF THE WORLD TODAY:

Their Organization, Development and Performance

CLAIR WILCOX, WILLIS D. WEATHERFORD, JR. and HOLLAND D. HUNTER. ■ A new supplement that offers concise assessments of five major economies—the Soviet Union, Great Britain, Communist China, India, and the United States. Includes analyses of such topics as individualism and collectivism, market economies, command economies, and those economies that are now either initiating development or have attained maturity. 148 pages, \$1.85

"It is superbly written, imaginative in its use of statistics and charts, and tied together in a matrix of up-to-date economic insights. . . . The treatment is compact, challenging, thoroughly objective and skillfully adapted to Socratic classroom techniques."—Theodore J. Kreps, Stanford University

THE DOLLAR IN CRISIS

Edited and with an introduction by SEYMOUR E. HARRIS. ■ A penetrating appraisal of the continuing dollar and gold problem by thirteen foremost authorities in international economics. 309 pages, \$3.95

"A fine collection of monographs which should be useful as collateral readings in such courses as Money and Banking, International Trade and Finance."—William A. Carter, Dartmouth College. "An important guide to professional opinions of the causes and the cures of the dollar crisis. It is all the more interesting because it contains numerous clues to the reasoning of some of the President's advisers."—*The New Republic*

CZECHOSLOVAK NATIONAL INCOME AND PRODUCT, 1947-1948 and 1955-1956

By Thad Paul Alton and Associates

Dr. Alton and his associates present an independent estimate of Czechoslovak national product for the years 1947-1948 and 1955-1956—the only estimate available. Using a fully articulated national accounting system, they show in the current market prices the transactions among the sectors of business enterprises, households, government, and the foreign sector. Derived from these accounts are the familiar national aggregates. Distorting elements in the market prices are identified, and the GNP is adjusted both by sectors of origin and by final uses, delineating the economic structure in terms of resource costs.

THE CHINESE INFLATION, 1937-1949

By Shun-hsin Chou

Using modern economic theory, Dr. Chou analyzes the inflationary spiral which disrupted the Chinese national economy: the monetary areas, the dual economy, demand-pull vs. cost-push, the effects of monetary factors on the inflation, and its social implications. The question of excess demand is examined with reference to each of the economic sectors, covering not only the process by which the inflationary pressures rose in each, but also the processes by which such pressures were diffused from one sector to another during the course of the inflation. The author demonstrates that the Chinese inflation was primarily a condition of "autonomous expansion of demand" (government spending and investment for ownership benefit) and "responsive price and wage increases."

Outstanding RONALD books . . .

FUNDAMENTALS of ECONOMICS

RUBY TURNER MORRIS, *Connecticut College*

Student-oriented throughout, this highly readable introductory textbook provides a broad background in economic theory and a detailed description of how the economic order operates. It offers a uni-

fied, balanced treatment of microeconomics and macroeconomics; stresses practical applications of theory. The analysis is distinguished for its clarity. 1961. 878 pp., *illus.* \$7.00

MONEY, BANKING, and MONETARY POLICY

CLIFTON H. KREPS, Jr., *University of North Carolina*

This important new textbook affords the student a thorough understanding of the national economic significance of monetary and banking policy. Theory is woven throughout in a highly integrated approach to the essential principles of money and banking. Attention is thus

focused on the "why" of institutional processes rather than the "how." The analytical discussion of the history of money and banking development places in true perspective the complex issues of theory and policy. 1962. 607 pp. \$7.50

ELEMENTS of BUSINESS ENTERPRISE

DWIGHT L. GENTRY and CHARLES A. TAFF—both *University of Maryland*

A balanced and teachable presentation of the entire scope of business administration. This textbook interrelates the functions of management and integrates the role of business enterprise in the so-

cial and economic order. It avoids confusing detail and treats all areas of operation and administration with proper emphasis. 1961. 705 pp., *illus.* \$7.00

ADVERTISING MANAGEMENT

NUGENT WEDDING, *University of Illinois*; and
RICHARD S. LESSLER, *Grey Advertising, Inc.*

NEW! This book provides a detailed and practical treatment of the concepts and principles underlying sound decision-making in advertising. Written by men of recognized authority in the field, it encourages the student to think criti-

cally and creatively on the all-important management functions involved in the profitable use of advertising in marketing goods and services. 1962. 620 pp., *illus.* \$8.50

Aspects of Labor Economics

Conference of the Universities-National Bureau Committee for Economic Research.

The eight studies included in *Aspects of Labor Economics* explore such areas as the economics of occupational licensing, the pecuniary and nonpecuniary income effects of monopoly and competition, and the "profitability and viability" of pre-Civil War American negro slavery as an industry. Wage differentials are analyzed from two different approaches: labor unions and their wage effects, and findings of recent research on relative differentials tested in the light of economic theories. *Published for the National Bureau of Economic Research.* 384 pages. Charts, tables. \$7.50

The Production and Distribution of Knowledge in the United States

By FRITZ MACHLUP

Investigating education, research and development, communications media, information machines, and information services, the author describes the allocation of human, fiscal, and natural resources in knowledge-production. The output of each field is evaluated in terms of its productivity and growth, and its contribution to the over-all body of knowledge. 400 pages. \$7.50

Research on Family Planning

Edited by CLYDE V. KISER

This volume describes and evaluates the current state of research and examines the likelihood of future progress in family planning. It discusses programs investigating attitudes toward family planning, effectiveness of specific birth control devices and techniques, and efficiency of areawide education and action. Particular attention is given to the problems of the developing areas and the difficulties of motivating the peoples of these countries to learn about, accept, and practice family planning. 700 pages. OXFORD BOOKS

OF EXCEPTIONAL INTEREST

CASE STUDIES IN EUROPEAN ECONOMIC UNION

By J. E. MEADE, H. H. LIESNER, and S. J. WELLS. Based on a study of the three long-established European economic unions—Belgian-Luxembourg Economic Union, Benelux, and the European Coal and Steel Community—this book tries to answer such questions as: can commercial unions be built without a unification of national tax policies and wage rates? can a partial union covering only some commodities work effectively if it does not cover other closely related activities? (*Royal Institute of International Affairs*)

\$6.10

NOMADS AND COMMISSARS

Mongolia Revisited

By OWEN LATTIMORE. A lively picture of Mongolia today, by the only American who has traveled in all the major regions of the China-Russia frontier and also speaks and reads the three most important languages of that frontier. Beginning with a geographical and historical survey, the author goes on to explain how Marxism succeeded in a country of nomads, and how Mongolia keeps its balance between the two giants of Communism. 8 pages of halftones; endpaper map.

\$5.75

THE AWAKENING OF SOUTHERN ITALY

By MARGARET CARLYLE. Beginning with a general discussion of the geographical and psychological factors that have contributed in the past to the poverty of southern Italy and Sicily, the author goes on to write from her own experience of the change in attitude towards this region since World War II, and of the real progress that has been made since 1950. 8 plates; map.

\$3.40

STUDIES IN INDUSTRIALIZATION IN NIGERIA AND THE CAMEROONS

By F. A. WELLS and W. A. WARMINGTON. Based on case studies of various individual industries and labor groups in Nigeria and the Cameroons during the years 1956 to 1961, this volume examines the many factors that have gone into the ever-increasing rate of industrialization in these two newly independent areas.

ECONOMISTS

AND

THE NATIONAL SECURITY

The Institute for Defense Analyses will appoint a small number of imaginative and highly capable economists for research involving foreign policy and national security. Research will be directly related to problems of the Office of Secretary of Defense, the Joint Chiefs of Staff, and other executive agencies of the government. This relationship affords an unparalleled opportunity both to the experienced economist and to the individual just embarking upon his career in economics.

Research projects may include military allocation and evaluation problems, arms control, civil defense, foreign military aid, and economic development, depending upon IDA's needs and the interests of its staff. Economists at IDA can explore vital

problems, and evolve new techniques, while making significant contributions to economic, military and foreign policy.

The favorable research environment includes encouragement of individual publication in IDA reports and professional journals. Those who wish will have an ample opportunity for interdisciplinary inquiries. And the IDA staff includes many outstanding physical scientists.

The Institute, a civilian, non-profit corporation, is sponsored by eleven of the major universities in the United States. For further information write the Assistant to the President, Institute for Defense Analyses, 1666 Connecticut Avenue, N.W., Washington 9, D.C. IDA is an equal opportunity employer.

PRINCIPLES OF ECONOMICS

C. E. Ferguson and Juanita M. Kreps,
both of Duke University

Aware of recent concern over economic growth and inflation, Professors Ferguson and Kreps have shifted the usual textbook emphasis to these problems. Their book is organized around the three currently dominant national objectives; (1) a relatively stable price level, (2) full and stable employment, (3) continued growth of per capita output. This clearly written book, with over 150 color illustrations, is planned for a one-year introductory course. 1962, 864 pp., \$7.95

NATIONAL INCOME:

ITS MEASUREMENT, DETERMINATION,
AND RELATION TO PUBLIC POLICY

Sam Rosen, University of New Hampshire

An upper-division and first year graduate text in macroeconomics and social accounting containing sections on income accounting, determination, and policy. Includes such relatively new devices as input-output, balanced budget multiplier, flow of funds, national balance sheets, and Phillips curve.

Jan. 1963, 384 pp., \$6.50 tentative

SOVIET UNION:

PARADOX AND CHANGE

Robert T. Holt and John E. Turner, both
of the University of Minnesota; et al.

This book neither condemns nor praises Russia, but rather tries to understand the quality of life in that changing country. City growth, economic changes, agricultural production, and technology are some of the areas studied by the authors who journeyed through Russia together and are experts on Soviet affairs.

ECONOMICS: THEORY AND PRACTICE

Melville J. Ulmer

This concisely written introduction to economics focuses on a clear, balanced coverage of four major areas: economic growth, income theory, theory of price and distribution, and world economics. A *Student's Manual* helps the student systematically to review the material in ECONOMICS by providing for each chapter and each appendix a series of true or false statements, multiple choice, and essay questions.

Studies in Comparative Economics

A new approach to the teaching of economics is presented in this series of volumes launched by an Inter-University Committee on Comparative Economics composed by leading American educators.

The Economics of Labor

BY E. H. PHELPS BROWN. Ranging widely in time and space, a British economist surveys the diversity of arrangements under which the world's work has been done—the varying status of the worker in the community and the changing relations between employer and employed. A mainspring of economic growth has been the improvement of the labor force, and the author asks how this has come about and how it can be promoted today. He asks also how the labor force gets deployed between different regions, industries, and occupations, in the traditional and authoritarian as well as in the market economies. cloth \$6.00; paper \$1.45

Foreign Trade and the National Economy

BY CHARLES P. KINDLEBERGER. Foreign trade has always been discussed in comparative terms, as the name of its most famous principle—the Law of Comparative Advantage—suggests. This book, however, is organized not by countries but analytically, and discusses two broad questions: (1) What determines the nature and amounts of the goods a country buys and sells in international trade? and (2) What is the impact of foreign trade on national economic life? cloth \$6.00; paper \$1.45

Price Formation in Natural Gas Fields

A Study of Competition, Monopsony, and Regulation

BY PAUL W. MACAVOY. The assumptions and objectives of national policy in the regulation of gas fields are subjected to close examination in this new volume in the Yale Studies in Economics. Mr. MacAvoy describes the characteristics of monopoly price formation, and of competitive and monopsony (buyer's monopoly) price formation, in order to see which corresponds most closely to actual field prices in recent years. \$6.75

Human Action

A Treatise on Economics

BY LUDWIG VON MISES. *New Revised Edition.* First published in 1949, this presentation of the point of view of a "conservative" economist has been reprinted five times. A revised edition is offered now as a new conservative movement gains strength in the United States. This is a systematic study of the manifold activities of human beings in search of food, shelter, and the variety of goods they have come to need. *Coming in April* \$15.00

FINANCIAL INSTITUTIONS—Their Role in the American Economy

by GILBERT COOKE, Bowling Green State University, CHARLES PRATHER, University of Texas, FRED CASE, University of California at Los Angeles and DOUGLAS BELLEMORE, New York University.

A comprehensive study of American financial institutions, organization, function and relation to the flow of funds in the money market. The book is authoritatively written, thorough in its coverage, and its fresh approach to financial decisions of the firm, the money market, working capital and credit, mortgage financing, and the capital market is characterized by unusual clarity and teachability.

501 pp. 6 x 9 Cloth \$7.75 (text edition)

COLLECTIVE BARGAINING—Principles, Practices and Cases

by MAURICE TROTТА, Associate Professor of Industrial Relations and Management, New York University.

Presents the historical and legal setting of the collective bargaining agreement and then the bargaining process in terms of organization and strategy and governmental and non-governmental aid to collective bargaining. A provocative treatment of the implementation of the labor contract follows. Scores of cases dealing with the problems of interpretation that have been the subject of arbitration are, in particular, fully covered.

Ca. 512 pp. 6 x 9 Cloth \$7.50 (text edition)

INTERNATIONAL FINANCE

by MAX J. WASSERMAN, CHARLES W. HULTMAN and LASZLO ZSOLDOS, all of the Patterson School of Diplomacy and International Commerce, University of Kentucky.

A thoroughly up-to-date basic treatment of international finance, clearly presented within a framework of the international monetary system which conditions it. With the dollar as the world's international and banking reserve money, the authors cover the U.S. balance of payments as a key phenomenon in international finance.

Ca. 368 pp. 6 x 9 Cloth \$7.50 (text edition)

PROBLEM MANUAL FOR INVESTMENTS

by DOUGLAS H. BELLEMORE and JULIAN G. BUCKLEY, both of the Graduate School of Business Administration, New York University.

A student's manual containing questions and problem materials for use in college courses in investments. While the manual is organized around the coverage of the subject as presented in Bellemore's INVESTMENTS, the material is basic to any beginning course in investments and may be used in connection with any standard textbook. The materials have been thoroughly class-tested and constitute an important new teaching aid in this field.

92 pp. 5½ x 8¼ Paper \$2.50

MANAGEMENT ACCOUNTING PROBLEMS

by WILLIAM H. CHILDS, Professor of Accounting, Hofstra College.

A collection of problems for those college courses in first year accounting which emphasize the management approach. The intensely practical nature of this problem material results from the fact that many of the problems have been taken from actual business situations. While this manual has been organized around a basic college textbook written by the same author (Childs' *Accounting For Management Control*) it may be readily adapted for use with any standard first year text. The case problems appeal particularly to teachers seeking rigor in the level of problem-working.

Ca. 186 pp. 8½ x 11 Paper \$2.75 (tentative)

NEW AND CURRENT TITLES

BUSINESS STATISTICS

2nd Edition—By John R. Stockton

The University of Texas

This book gives the student sufficient acquaintance with the most commonly used methods of analysis and enables him to use statistical data effectively in making business decisions. A laboratory manual and 57 transparencies for use on an overhead projector are available for the second edition of this popular textbook.

BUSINESS CYCLES AND FORECASTING

2nd Edition—By Carl A. Dauten

Washington University, St. Louis

Six new chapters are included to provide increased emphasis on economic theory. The second edition provides an analytical presentation of cycle theory, forecasting principles, and policies for economic stability.

PREFACE TO ECONOMETRICS

By Michael J. Brennan, Brown University

Here is an introduction to quantitative methods that can be understood by the undergraduate. Emphasis is placed on applications of economic theory, quantitative measurement, and tests of correctness of theory. Problems conclude each chapter.

AMERICAN AND BRITISH TECHNOLOGY IN THE NINETEENTH CENTURY

By H. J. Habakkuk

*Chichele Professor of Economic History in the
University of Oxford*

Why did some countries invent and adopt mechanical methods more rapidly than others? Was the cause one of finance and labour, or the rate of growth of the market? Professor Habakkuk avoids the ready answer, too pat and perfect to reveal the complex nature of technological growth. Instead he allows the comparative history of American and British progress to form theses with built-in qualifications, with nuances underlined, with exceptions a part of the rule. The attitudes of entrepreneurs, the influence of forms of industrial organization on the choice of techniques, the difficulties of borrowing a technology from another country, the relations of economic growth and technical progress—all these are an integral part of his argument and his answer.

"Neither of these theses—the response to a scarcity of labour and 'the penalty of taking the lead'—is new. But what is here, in this lucid and sinewy discussion, is a closer and more critical examination of them, illumined with a more confident reference to the technological record, than we have had before. And, in passing, it indicates many promising byroads for more detailed inquiry by other economic historians."—*The Economist*

MARKET THEORY AND THE PRICE SYSTEM

**By ISRAEL M. KIRZNER, Associate Professor of Economics,
New York University**

This provocative new text is designed for use in an undergraduate course in intermediate price theory. Focusing on the market, market prices and resource allocation as achieved through the market, the text adopts the approach that the market is essentially a process of adjustment between individual market participants in response to the patterns imposed by the activities of others. Decision making and activity on the part of individuals, especially the entrepreneur, is seen as centrally important to the market process; and market theory, in the view of the author, consists of an analysis of the step-by-step adjustments these decisions stimulate and the way the information required for these adjustments is communicated. Emphasis is on the kind of change that can be expected when there is *disequilibrium*, and equilibrium positions are not treated as important in themselves. Diagrams illustrate economic principles and serve as an aid in grasping the logic involved; the result is a theoretical text which provides the student with the opportunity to consciously exercise economic reasoning in abstract terms.

OXFORD texts in economics

ECONOMICS

By ABRAHAM L. GITLOW, New York University

Combining careful analysis, thorough application of economic theory and a lively writing style, this volume is a sound, up-to-date text for introductory courses in economics. Its central unifying theme is a major issue of our times—the contest between a free market system and economic authoritarianism. Economic growth, full employment, national security, and social welfare are among the principal contemporary problems viewed as aspects of the basic theme. Chapter summaries and extensive bibliographies are included.

1962 768 pages 175 figs. and tables \$7.50

ECONOMICS WORKBOOK

By ABRAHAM L. GITLOW and DANIEL E. DIAMOND.

1962 160 pages paperbound \$2.00

READINGS IN ECONOMICS AND POLITICS

Edited by H. C. HARLAN

The articles in this absorbing collection focus on twelve basic political-economic problems, among them: agriculture, business, capital, labor, taxation, monetary and fiscal policy, inflation, employment, and economic foreign policy.

1961 704 pages paperbound \$2.75

PROBLEMS OF AMERICAN ECONOMIC GROWTH

By BRUCE R. MORRIS, University of Massachusetts

Written at an elementary level of analysis, this text challenges the student to examine and formulate his own solutions to the major issues concerning economic growth in the United States. A wide variety of problems are covered, including raw materials, labor supply, capital, government expenditures, technological change, and relations with other economies.

1961 256 pages paperbound \$2.50

MONEY AND INCOME:

An Outline of Monetary Economics

By A. C. L. DAY, London School of Economics, and
S. T. BEZA, Princeton University

A careful survey of modern macro-economic theory, including substantial coverage of United States monetary history and institutions.

1960 640 pp. illus. \$7.50

TOWARDS A MORE GENERAL THEORY OF VALUE

By EDWARD H. CHAMBERLIN, Harvard University

Sixteen essays on Professor Chamberlin's theory of monopolistic competition, its development and its application to specific economic problems.

THE COLLEGE DIVISION OF ALLYN AND BACON INVITES YOU TO EXAMINE THE FOLLOWING TEXTS

Designed to accompany any basic economics text, the presentation reflects a new approach in the arrangement of subject matter. The text consists of six sections to give the student an introduction to economics and its methodology as well as development. Included are the basics of micro and macro theory, and an examination of international economic problems.

CONTEMPORARY ECONOMICS: SELECTED READINGS

by REUBEN E. SLESINGER and
ASHER ISAACS

The text integrates basic supply and demand analysis with an analysis of economic problems. Price theory is approached in terms of total cost—total revenue; then marginal cost—marginal revenue. The authors present a detailed treatment of the economic development of the Western World along with the simultaneous development of economic doctrines.

ECONOMICS: PRINCIPLES, PROBLEMS & PERSPECTIVES

By HOWARD S. DYE, JOHN R.
MOORE and J. FRED HOLLY

This second edition of a popular text includes a great deal of new material and revisions. Probability has been expanded to include formal discussions of joint, conditional, and marginal probability. The authors stress the concepts underlying statistical methods to lead the student toward a fuller understanding of the use of statistical techniques as tools of management decision-making.

FUNDAMENTAL STATISTICS FOR BUSINESS AND ECONOMICS, 2ND ED.

by JOHN NETER and
WILLIAM WASSERMAN

This combination workbook and study guide contains a multitude of practice problems and practical examples of statistics as used in business and industry. Designed primarily to help the student evaluate his own progress, the workbook facilitates the grading of assignments, and provides additional examples and illustrations for lecture problems.

THE EXPERIENCE OF ECONOMIC GROWTH

Case Studies in Economic History

by **BARRY E. SUPPLE**, *University of Sussex*

Effectively organized to introduce the student to the historical experience of economic growth as exemplified in the industrialized countries, this outstanding new reader marks a first in its field. The editor's lucid, comprehensive introduction unifies an invaluable, remarkably varied collection of scholarly essays.

February 1963; 448 pages; \$6.95 text

READINGS IN BUSINESS FLUCTUATIONS, GROWTH, AND STABILIZATION

by **JOHN J. CLARK**, *and* **MORRIS COHEN**,

St. John's University *Associate Editor, Fortune Magazine*

These carefully selected readings from the most eminent classical and contemporary thinkers represent, in effect, a major assessment of the advantages and limitations of the system of private enterprise. Providing a thoroughly logical and orderly examination of our own economic structure in the face of serious Soviet economic rivalry, this superb new collection brings together the subject's most significant literature.

Spring 1963; about 600 pages; \$6.50 text

TRADE UNIONS IN THE AGE OF AFFLUENCE

by **WILLIAM H. MIERNYK**, *University of Colorado*

A lucidly written survey of the growth of trade unions and the evolution of collective bargaining in the United States. This title initiates the new Random House Studies in Economics series.

NOTICE

To MEMBERS and SUBSCRIBERS

INCREASE IN RATES

At the March 23-24, 1962, meeting of the Executive Committee of the Association, it was decided to adopt the following rate schedule, effective as of January 1, 1963:

Annual dues	\$ 8.00
Family membership	1.00
Junior (student) membership	4.00
Subscribing membership	10.00
Contributing membership	25.00 or more
Subscription to the <i>A. E. R.</i>	8.00

The members of the Executive Committee felt this action was necessary to enable the Association to continue present services to its members and to meet rising publishing costs of the *American Economic Review* and a new edition of the *Handbook*. It should be noted that membership dues and subscription rates have not been changed since 1950. The present schedule of rates is well below that of most other professional organizations.

The Econometric Society is an international society for the advancement of economic theory in its relation to statistics and mathematics.

Subscriptions to *ECONOMETRICA* and inquiries about the work of the Society and the procedure in applying for membership should be addressed to Richard Ruggles, Secretary, The Econometric Society, Yale University, Box 1264, New Haven, Connecticut, U.S.A.

MONOGRAPH

Series of

The American Academy of Political and Social Science

Publishers since 1890 of *THE ANNALS*

Presents a study of the political science discipline through recurring patterns in the behavior of individuals and groups involved in government and politics.

The Limits of Behavioralism in Political Science

Edited by James C. Charlesworth, Professor of Political Science, University of Pennsylvania and President, The American Academy of Political and Social Science

with papers by

David Easton
Heinz Eulau

Russell Kirk
Mulford Q. Sibley

Richard C. Snyder

First in the current series, these five papers discuss the interrelationship between behaviorism or "behavioralism" and political science. "Behavioralism," as distinguished from "behaviorism," is a word that cannot be defined in a sentence; but, whatever it is, it has generated a great deal of wonderment, controversy, missionary zeal, and scorn in many segments of the confraternity of political scientists.

The Academy is proud to assemble this distinguished panel of contributors to an elucidation of this current and controversial topic.

ECONOMIC CENSUS STUDIES

This series of monographs is based mainly on the economics censuses of 1954 and subsequent years, and is prepared under the auspices of the Committee on Analysis of Economic Census Data, which was appointed by the Social Science Research Council in 1956. The committee is principally concerned with stimulating more informed use, in economic analysis, of the large body of economic data collected by the Bureau of Census. As a part of its regular activities the Bureau gathers a vast amount of data, only some of which are generally available in published form. When properly analyzed, these data can shed a great deal of light on the structure and functioning of the United States economy.

Changes in the Location of Manufacturing in the United States Since 1929

by Victor R. Fuchs

Since 1929 there has been a significant shift in the location of manufacturing in the United States which has had and will continue to have a profound effect on the nation's economic, political, and social life. In this first volume of the Economic Census Studies, the author presents a comprehensive description and analysis of these changes. Mr. Fuchs investigates the determinants of manufacturing growth by state and region, considering the relation between growth of manufacturing and wage rates, extent of unionization, climate, and other location factors.

\$10.00

Planning for Freedom

by Eugene V. Rostow

The Dean of the Yale Law School appraises the legal system for governing and directing the economy of the United States as a means through which we seek the goals of personal social freedom under law. "Meaty, clear, thoughtful, and filled with obiter dicta on, among other matters, education, foreign policy, our farm and transportation problems."—*American Economic Review*.

The National Wealth of the United States in the Postwar Period

By Raymond W. Goldsmith

This report contains the only comprehensive, detailed estimates of U. S. national wealth and its components since World War II, showing that our national wealth nearly tripled between 1945 and 1958. The figures expand the author's 1900-1945 estimates, published in his *A Study of Saving in the United States, Vol. III*. This present book also investigates the structure of our national wealth, how it has changed during the postwar period, and how it compares with that of other countries for which similar estimates exist. *Published for the National Bureau of Economic Research.*

448 pages. Tables & charts. \$12.50

Diversification & Integration in American Industry

By Michael Gort

A study which provides the first comprehensive view of the inter-industry structure of the large diversified enterprise, using unpublished tabulations of the Bureau of the Census. While only a small proportion of companies in the United States are active in more than one industry, those that are diversified constitute an important part of the economy and their activities outside their own industry are large in the aggregate. *Published for the National Bureau of Economic Research.*

275 pages. Tables & charts. \$5.00

The Flow-of-Funds Approach to Social Accounting:

Appraisals, Analysis and Applications

Conference on Research in Income and Wealth, 26

Part I of this volume contains papers dealing with the integration of the flow-of-funds accounts with other social accounting systems. Part II relates to the analytic uses and applications of flow-of-funds data in economics, finance, business, and government. Discussions of sources of information such as financial institutions, unincorporated businesses, and consumers, are included in Part III. *Published for the National Bureau of Economic Research.*

Risk and Insurance

by
James L. Athearn
of the
**University of
Florida**

Written in clear, nontechnical language, this new book applies the modern concept of risk to teaching the principles of insurance. Showing the risk first, the author discusses the insurance to cope with it from the point of view of the buyer of insurance, the risk manager. Throughout the book, Professor Athearn explains the nature of insurance from a broad economic standpoint rather than from the restricted view of the insurance industry alone.

526 pages, illus. \$6.95

"Professor Athearn in using the approach of risk management has written one of the best introductory texts." **Dean Edmund A. Smith**, University of Portland, Oregon.

TWO TIMELY TITLES

INTERNATIONAL TRADE

THEORY-POLICY-PRACTICE

By Kramer, d'Arlin, and Root

Here is a noteworthy contribution to the instructional literature for the courses in international trade and international economics. It is written by three authorities who are adequately qualified to deal with international economic theory, international economic policy, and the practical problems of the international trading firm.

The emphasis is on the international role of the United States since World War II and its efforts to create a world trading system of free exchange and low trade barriers. Attention is also pointed to other international developments such as the European Economic Community. A summary of important points is given at the end of each chapter.

678 pages

\$7.95

INTERNATIONAL MARKETING

By Roland L. Kramer

This dual-purpose book is designed for use in the marketing department and also in the foreign trade department. Basic principles of marketing are discussed in a manner that provides a clear contrast between domestic marketing and foreign marketing. Practical examples and applications are used to give the student a grasp of the framework in which marketing on a world-wide basis operates.

Each chapter concludes with a concise summary of outstanding points and principles. The end-of-chapter problems present practical situations involving investigation, research, and outside study.

The Experience of Economic Growth

by BARRY SUPPLE, *McGill University*

This outstanding collection of essays introduces the student to the history of economic growth as shown by the industrialized countries of the world. The book, divided into five sections, gives representative views of numerous well-known scholars in the field. In an explicit and detailed introductory essay, Professor Supple draws these divergent views together as he discusses the broad features of economic growth both in theory and in history.

Spring 1963

Business Fluctuation, Growth, and Stabilization

by JOHN J. CLARK, *St. John's University*
and MORRIS COHEN, *Associate Editor, Fortune Magazine*

A superb anthology of articles and excerpts from the best of classical and contemporary professional literature. The main challenge to private enterprise, according to the editors, is to contain business fluctuation within reasonable limits without destroying the incentives which stimulate economic growth. This examination of the evolution of economic theory since the middle of the nineteenth century provides an orderly appraisal in depth of our economic structure in the face of serious Soviet rivalry.

Spring 1963

Trade Unions in the Age of Affluence

by WILLIAM H. MIERNYK, *University of Colorado*

This is the first book in the Random House Studies in Economics, a series of original works attractively bound in paper covers.

MONEY, BANKING & PUBLIC POLICY

By HAROLD BARGER, Columbia University

1962
714 pages
\$7.00 list

A new, up-to-date presentation of contemporary banking. The author's fresh approach includes such timely additions as: discussion of banking in other countries, monetary aspects of the business cycle, a systematic discussion of major policy issues of our times, and a lucid description of bank and non-bank financial institutions—the way they operate, and policy problems connected with their regulation.

A widely commended source

READINGS ON THE SOVIET ECONOMY

By FRANKLYN D. HOLZMAN, Tufts University

1962
763 pages
\$5.95 list

A collection of 41 of the best essays published on the Soviet economy in the past twenty years. The book treats the Soviet system in ten major areas, including articles on theory, statistics, and descriptions of institutions. In almost every section there are articles that compare the Soviet progress with that of the United States and other Western nations.

New, penetrating treatment

NATIONAL INCOME AND ECONOMIC GROWTH

By KENNETH K. KURIHARA, Rutgers University

1961
176 pages
\$4.25 list

A well-written book that presents a more comprehensive treatment of economic growth than the prevailing national income texts. The author integrates a useful review of the essentials of national income accounting with a clear, yet vigorous treatment of income and employment theory and an operationally significant introduction to the growth theory. Written for courses in macroeconomic theory.

Brookings Titles —Forthcoming and Recent

Federal Fiscal Policy in the Postwar Recessions, by Wilfred Lewis. Describes, measures, and evaluates both automatic and discretionary responses to changes in economic activity. The first in the new series of Studies of Government Finance. About 400 pages. (November) Cloth, \$6.75. College Edition, paper \$2.50

India's Quiet Crisis: Economic Development and American Policy, by John P. Lewis. The author, whose research included a year's stay in India, explains the importance of the Indian experiment both to India and the United States. Analyzes the importance of planning and of American aid. About 400 pages (November) \$5.75

• Just Published

Tax Credits and Intergovernmental Fiscal Relations, by James A. Maxwell. The possibilities of easing the financial burden on state and local governments and of coordinating federal and state-local revenue systems are explored in this study of tax credits, tax sharing, grants, and tax supplements. 202 pages \$3.75

Competition and Monopoly: Legal and Economic Issues, by Mark S. Massel. Examines the impact of the full range of government activities affecting competition—not just antitrust, but government purchasing, research, taxation and other policies as well. Points to the need for better understanding between economists and lawyers so that economic analysis can be more effectively used. 477 pages \$6.75

• Other Recent Titles

Wage Policy and Long-Term Contracts, by Joseph W. Garbarino Paper \$2.00

Development of the Emerging Countries: An Agenda for Research, by Robert E. Asher, Everett E. Hagen, Albert O. Hirschman, Gerhard Colm, Theodore Geiger, Arthur T. Mosher, R. S. Eckaus, Mary Jean Bowman, C. Arnold Anderson and Howard Wiggins Paper \$2.75

Competition as a Dynamic Process, by John Maurice Clark \$7.50

The Role of the Federal Government in Financing Higher Education, by Alice M. Rivlin Paper \$2.00

PRINCIPLES OF ECONOMICS

C. E. Ferguson and Juanita M. Kreps,
both of Duke University

Aware of recent concern over economic growth and inflation, Professors Ferguson and Kreps have shifted the usual textbook emphasis to these problems. Their book is organized around the three currently dominant national objectives; (1) a relatively stable price level, (2) full and stable employment, (3) continued growth of per capita output. This clearly written book, with over 150 color illustrations, is planned for a one-year introductory course. 1962, 864 pp., \$7.95

NATIONAL INCOME:

ITS MEASUREMENT, DETERMINATION,
AND RELATION TO PUBLIC POLICY

Sam Rosen, University of New Hampshire

An upper-division and first year graduate text in macroeconomics and social accounting containing sections on income accounting, determination, and policy. Includes such relatively new devices as input-output, balanced budget multiplier, flow of funds, national balance sheets, and Phillips curve.

Jan. 1963, 384 pp., \$6.50 tentative

SOVIET UNION:

PARADOX AND CHANGE

Robert T. Holt and John E. Turner, both
of the University of Minnesota; et al.

This book neither condemns nor praises Russia, but rather tries to understand the quality of life in that changing country. City growth, economic changes, agricultural production, and technology are some of the areas studied by the authors who journeyed through Russia together and are experts on Soviet affairs.

Nov. 1962, 256 pp., \$4.50 tentative

\$50,000,000,000

... or 1/10 of the national income, represents the sum of resources spent by our military establishment each year. The Department of Defense, viewed as a giant, multi-product, multi-location firm, exhibits resource allocation problems of great complexity and of a magnitude unparalleled in history.

The Institute for Defense Analyses is intimately concerned with the solution or alleviation of these problems, and with other matters important to the Secretary of Defense and the Joint Chiefs of Staff. In this work, a serious need exists for experienced economists to pool their talents and their points of view with those of IDA scientists, as colleagues in joint endeavors. IDA is a civilian, nonprofit corporation sponsored by eleven of the nation's great universities. At IDA you will enjoy a continuing intellectual challenge, a favorable research environment, and the gratification of doing work of national significance.

IDA is an equal opportunity employer. For further information, contact Mr. J. P. Rumberger, Director of Personnel

Harvard Presents

UNITED EUROPE Challenge and Opportunity

By Walter Hallstein

Mr. Hallstein, President of the Commission of the European Economic Community, opens with a brief survey of existing European treaties concerning economic integration: Euratom, dealing with atomic energy; ECSC (European Coal and Steel Community); EEC (European Economic Community or "Common Market"). According to the author "... it is clear that the words 'economic union' are inadequate to describe the European Economic Community. We are witnessing a 'continual revolution' today, one in which the European Community has no small share." He ends his discussion with his predictions on the possible future of the Common Market. *The William E. Clayton Lectures, 1962.* \$2.75

ECONOMIC BACKWARDNESS IN HISTORICAL PERSPECTIVE

A Book of Essays

By Alexander Gerschenkron

Explaining and systematizing the elements of innovation in industrial history, Mr. Gerschenkron opens new paths of research and poses a number of questions concerning economic development in backward countries. His versatile analysis includes not only industrial output indices and historical hypotheses on the index number problem, but also insights from a study of Soviet novels and a brilliant critique of *Doctor Zhivago*. \$8.75

OLIGOPOLY AND TECHNICAL PROCESS

By Paolo Sylos-Labini

The author believes that mainly as a consequence of industrial concentration the modern structure of production in advanced countries differs significantly from that of the past century. In industrial markets concentrated and differentiated oligopoly has taken the place of quasi-competitive conditions. *Harvard Economic Studies.* \$4.75

Announcing . . .

Programmed Instruction in Economics

In 1961 the National Task Force on Economic Education said:

"We believe it is far more important for students to learn to think about economic situations objectively and rationalize for themselves than to learn masses of institutional details, or memorize lists of unused economic concepts. . . . What they study should be studied *analytically* and in reasonable depth rather than as superficial memory work."

Concurrent with the heightened appreciation of analysis in teaching economic concepts, psychologists have introduced *programmed instruction*, a new teaching technique that facilitates the analytical study of concepts.

With programmed instruction, sometimes called the "teaching machine" method, the student

- progresses in small steps arranged in a carefully planned sequence
- gets prompt confirmation or knowledge of results at each step
- proceeds at his own pace
- makes few discouraging errors

This procedure requires the student to take an active part in the step-by-step analysis of economic concepts. First, he identifies the critical variables in a description of economic behavior. Then he manipulates the variables to discover the relationship between them. Finally, he summarizes his discovery in a verbal or graphic statement of the principle.

* * *

In association with Irwin Herrnstadt of Northeastern University, ENTELEK has developed five programmed instructional supplements, each fully explaining a conceptual "stumbling block" in introductory economics:

- Supply and Demand
- National Income Accounting
- Theory of Income Determination
- The Business Firm
- Theory of Production

Each topic is treated in a separate volume. Each volume is in two sections. One section contains the programmed "dialogue," about 600 frames long, which guides the student through the analysis. The other section contains correlated tables and graphics.

The five programmed supplements can be used in conjunction with any introductory economics text or with a TV lecture series. A "key" supplied with the program correlates the supplements with specific texts and a current ETV series.

The program has been thoroughly tested with college freshmen and high school populations.

Write for approval copies.

Each supplement: 8½ x 11 inches, c. 130 pages \$2.00

ORGANIZATION THEORY AND INDUSTRIAL PRACTICE

A SYMPOSIUM OF THE FOUNDATION FOR RESEARCH ON HUMAN BEHAVIOR

Edited by M. HAIRE, University of California, Berkeley. Representatives of industry present papers on organization-theory-in-action. 1962. 173 pages. \$5.75.

BASIC MATHEMATICS FOR ADMINISTRATION

By F. P. FOWLER, JR. and E. W. SANDBERG, both of Colorado State University. Provides fundamental tools to help cope with the increasingly complex problems of today's science of administration. 1962. 339 pages. \$7.95.

CASEBOOK IN PRODUCTION MANAGEMENT

By R. J. ZIEGLER, University of Illinois. Specifically designed to serve as a bridge between present methods of teaching production management and those which may ultimately emerge in the future. 1962. 150 pages. \$5.50 (hardbound). \$3.95 (paperbound).

AGING AND PERSONALITY

A STUDY OF EIGHTY-SEVEN OLDER MEN

By the late S. REICHARD, formerly of the University of California, Berkeley; F. LIVSON, University of California, Berkeley and P. G. PETERSEN, Solano County Mental Health Service, Fairfield, California. A report on the study directed by the late Else Frenkel-Brunswik. Examines the transition period from middle-age to old-age, as observed in a group of normal working men. 1962. 237 pages. \$7.95.

THE STATISTICAL METHOD IN BUSINESS

By F. A. EKEBLAD, Northwestern University. Deals with the statistical method in its applications to the problems of business. 1962. 789 pages. \$8.50.

QUALITY CONTROL AND APPLIED STATISTICS

AN ABSTRACT SERVICE FOR ALL BRANCHES OF INDUSTRY

Edited by R. S. TITCHEN, A. J. ROSENTHAL, B. BOLLERMAN and F. NISTICO. An Interscience Publication. Volume VII, 1962. Subscription price of this abstract is \$90.00 per year (12 issues).

OPERATIONS RESEARCH/MANAGEMENT SCIENCE

INTERNATIONAL LITERATURE DIGEST SERVICE. A MONTHLY SERVICE TO MANAGEMENT—BUSINESS, INDUSTRIAL, MILITARY.

Edited by R. S. TITCHEN and A. J. ROSENTHAL. An Interscience Publication. Volume II, 1962. Subscription price is \$75.00 per year (12 issues).

NOTICE

To MEMBERS and SUBSCRIBERS

INCREASE IN RATES

At the March 23-24, 1962, meeting of the Executive Committee of the Association, it was decided to adopt the following rate schedule, effective as of January 1, 1963:

Annual dues	\$ 8.00
Family membership	1.00
Junior (student) membership	4.00
Subscribing membership	10.00
Contributing membership	25.00 or more
Subscription to the <i>A. E. R.</i>	8.00

The members of the Executive Committee felt this action was necessary to enable the Association to continue present services to its members and to meet rising publishing costs of the *American Economic Review* and a new edition of the *Handbook*. It should be noted that membership dues and subscription rates have not been changed since 1950. The present schedule of rates is well below that of most other professional organizations.

S-AA-7 AUTOMATION AND TECHNOLOGICAL CHANGE

An American Assembly Book edited by John T. Dunlop, Harvard University.

Nine leading authorities consider the possibilities of advancing industrial technology: if oriented toward human values, it could mean a better age for mankind—or it could impose a mechanical jig on its creators. 192 pp. (orig.), 1962, paperback \$1.95, clothbound \$3.95.

S-44 THE AMERICAN LABOR MOVEMENT

edited by Leon Litwack, University of Wisconsin.

Reveals the American worker's struggle under the impact of the Industrial Revolution. Throws new light on topics of increasing concern. Retraces the turbulent course of the American labor movement through the give and take of editorials, periodicals and Congressional hearings. 192 pp. (orig.), October 1962, paperback \$1.95.

S-38 SOCIAL JUSTICE

edited by R. B. Brandt, Swarthmore College.

The concept of justice—as seen by the economist, philosopher, lawyer and political theorist. This is the first book-length treatment to use modern analytic concepts drawn from philosophy. 192 pp. (orig.), October 1962, paperback \$1.95, clothbound \$3.95.

S-23 REVOLUTION, EVOLUTION AND THE ECONOMIC ORDER

by Allen M. Sievers, University of Florida. Sharp contrast of views drawn from the works of Schumpeter, Gailbraith, Hansen, Clark, Keynes, and author Sievers. 192 pp. (orig.), 1962, paperback \$1.95, clothbound \$3.95.

S-11 WHAT PRICE ECONOMIC GROWTH?

edited by Klaus Knorr and William J. Baumol, both of Princeton University. 174 pp. (orig.), 1961, paperback \$1.95, clothbound \$3.95.

S-12 SCARCITY AND EVIL

by Vivian Charles Walsh, University of Buffalo. 128 pp. (orig.), 1961, paperback \$1.95, clothbound \$3.95.

S-AA-3 GOALS FOR AMERICANS

The Report of the President's Commission on National Goals, 372 pp. (orig.), 1960, paperback \$1.00.

THE SUPPLY AND PRICE OF NATURAL GAS

By

M. A. ADELMAN

Professor of Economics, Massachusetts Institute of Technology

Demy 8vo 30s. (\$4.20) net (to subscribers to *The Journal of Industrial Economics*, 15s. (\$2.10))

The study analyzes the nature of costs in petroleum (including both oil and gas), and concludes that the industry is one where costs increase with greater output, so that there is no inherent tendency to chronic surplus and breakdown, and no natural monopoly.

Joint costs in oil-gas production are then analyzed. The notion of "by-products" is rejected; the distinction is drawn between natural gas associated with oil, produced in proportions fixed by nature and therefore with near-zero marginal cost and little response to price changes; and non-associated (often mistitled "dry") gas, a joint product in variable proportion with a marginal cost schedule and where price therefore determines supply.

U. S. data on the supply and price of non-associated gas are then examined, on the assumption that its experience has some predictive value elsewhere. The concluding section first sketches the world crude oil market today, the surplus of supply, downward pressure on prices, and the sometimes paradoxical effects on the bargaining over profit shares. Particular attention is paid to Soviet gas development.

FROM THE FREE PRESS FALL LIST IN ECONOMICS

Main Currents in Modern Economics Economic Thought Since 1870

By Ben B. Seligman

This book provides the first critical examination of *all* major strands of modern economic thought, from the nineteenth century anti-classical revolts to the most recent developments. Mr. Seligman approaches his subject historically, treating the evolution of doctrine in terms of successive responses to the challenges of ever-shifting environment.

The organization is based on major schools of thought, allowing students to trace the development of each body of theory through all its typical phases: promulgation, critical attack, empirical testing, and logical refinement.

Just published, 887 pages, \$11.75

THE ECONOMICS OF EDUCATION

By John Vaizey, University of London Institute of Education

Education as an *economic* resource is the subject of this pioneering work. It focuses on the role of education in economic growth — investment in human beings... returns... measuring productivity... role in public finance. The author also explores how to provide for expansion of education programs most fruitfully and efficiently.

Just published, \$4.00

PROSPECTS FOR INDIAN DEVELOPMENT

By Wilfred Malenbaum, University of Pennsylvania

The author analyzes Indian economic progress in the last decade as a basis for assessing the possibilities for the future — particularly under the third five-year plan, which runs until 1966. This book is the first to treat Indian economic growth as a comprehensive process rather than as a government program. It emphasizes the interplay between private and public activities.

Just published, \$6.00

SOME ASPECTS OF INDUSTRIAL FINANCE IN INDIA

By George Rosen, United Nations

This book examines capital markets, banks, and special financial institutions in India, carefully evaluating their contributions to economic growth. The author uses empirical data to develop an appropriate theoretical framework—from which useful lessons can be drawn for dealing with the standard economic problems of underdeveloped countries.

NOTICE

To MEMBERS and SUBSCRIBERS

INCREASE IN RATES

At the March 23-24, 1962, meeting of the Executive Committee of the Association, it was decided to adopt the following rate schedule, effective as of January 1, 1963:

Annual dues	\$ 8.00
Family membership	1.00
Junior (student) membership	4.00
Subscribing membership	10.00
Contributing membership	25.00 or more
Subscription to the <i>A. E. R.</i>	8.00

The members of the Executive Committee felt this action was necessary to enable the Association to continue present services to its members and to meet rising publishing costs of the *American Economic Review* and a new edition of the *Handbook*. It should be noted that membership dues and subscription rates have not been changed since 1950. The present schedule of rates is well below that of most other professional organizations.

*The College Department
Of Rand McNally Announces*

**MONEY, BANKING,
AND PUBLIC POLICY**

by **HAROLD BARGER** • *Columbia University*

Carefully organized and well-written, this text treats fully all topics necessary for a firm foundation in understanding contemporary banking. The author's fresh approach includes such timely and important additions as discussion of banking in other countries and the monetary aspects of the business cycle. His classroom experience offers the student a more balanced, integrated and thought-provoking treatment of theory, description, and policy than any previous text.

FOUR OUTSTANDING FEATURES OF THIS NEW TEXT ARE:

1. A lucid description of bank and nonbank financial institutions, of the way they operate, and of policy problems connected with their regulation.
2. A compact, yet up-to-date and well-balanced account of monetary and fiscal theory. This account proceeds step by step with ample arithmetical and graphical illustrations, free from frills, and gives the student the basic understanding he needs for the discussion of policy problems.
3. A systematic discussion of the major policy issues of our time in a relevant historical setting. The potentialities of monetary and fiscal policy are appraised in relation to growth, unemployment, inflation and the gold problem.
4. A comprehensive treatment of contemporary banking with less emphasis on the extraneous details of banking history which plague the ordinary text.

Economics in Perspective

from Holt, Rinehart and Winston

PRINCIPLES OF ECONOMICS

C. E. Ferguson and Juanita M. Kreps, both of Duke University

Aware of recent governmental and academic concern over economic growth and inflation, Professors Ferguson and Kreps have shifted the usual textbook emphasis to these problems. Their book is organized around the three currently dominant national objectives; (1) a relatively stable price level, (2) full and stable employment, (3) continued growth of per capita output. In addition to traditional materials, the authors extensively discuss such newer devices and problems as cost-push inflation, national wage policy, non-profit maximizing theory, input-output, and gold outflow. This clearly written book is designed for a one-year introductory course. Over 150 color illustrations. *March 1962, 800 pp., \$8.00 tentative*

ECONOMIC PERFORMANCE

An Introduction to Economics

Henry H. Villard, City College of New York

An unconventional and unique approach to the understanding of basic economic issues. How economies perform and the reasons for their individual stages of achievement: these are the major themes. Today's various economic systems—advanced and underdeveloped, enterprise and collectivist—are given careful attention. Includes estimates of waste due to malperformance both in achieving full employment and in economizing, and summaries of possible improvements in existing economies. *1961. 672 pp., \$6.50*

NATIONAL INCOME

Its Measurement, Determination and Relation to Public Policy

Sam Rosen, University of New Hampshire

An upper-division and first year graduate text in macroeconomics and social accounting containing sections on income accounting, determination, and policy. Includes such new devices as input-output, balanced budget multiplier, flow of funds, national balance sheets, and Phillips curve. *Aug. 1962, 450 pp., \$7.00 tentative*

From Harcourt, Brace & World

THE DOLLAR IN CRISIS

Edited, with an introduction,
by SEYMOUR E. HARRIS, *Lucius Littauer*
Professor of Political Economy, Harvard University

Thirteen foremost authorities in international economics analyze the crucial dollar and gold problem in this new and thorough paperback study. Nearly all the essays were especially commissioned for this book; they present influential, often conflicting points of view and provide the kind of contemporary interpretations that are suitable for a variety of courses in economics. 309 pages, \$3.45

UNIONS, MANAGEMENT, AND THE PUBLIC: Second Edition

E. WIGHT BAKKE, *Yale University*
CLARK KERR, *University of California*
CHARLES W. ANROD, *Loyola University, Chicago*

A comprehensive, up-to-date collection of classical and modern readings, with editorial commentary, covering the entire industrial relations field, its problems and policies. Three-fourths of this edition consists of new materials. "This revision maintains the same high quality which the first edition had, and I consider it one of the outstanding books of readings in industrial relations now available."—CHARLES A. MYERS, Massachusetts Institute of Technology. *An Instructional and Study Guide accompanies this text.* 650 pages, \$6.95

CONCEPTS AND CASES IN ECONOMIC ANALYSIS

AARON W. WARNER, *Columbia University*
VICTOR R. FUCHS, *New York University*

The emphasis throughout this text-casebook is on the proper use of concepts and tools of economic analysis in specific situations. The illustrative materials—188 cases in all—are extracted from many sources, including newspaper items, reports of congressional hearings, articles from professional journals and quotations from classic economic literature. This range of selections is designed to give the student a firm foundation for understanding economic theory and for solving economic problems. *Paperbound, 288 pages, \$3.00*

An Instructor's Key is available.

Books for Courses in Economics

ECONOMIES OF THE WORLD TODAY

CLAIR WILCOX, *Swarthmore College*

HOLLAND HUNTER, *Haverford College*

WILLIS D. WEATHERFORD, *Swarthmore College*

This new paperback supplement for the introductory course offers an illuminating assessment of five major economies—the Soviet Union, Great Britain, Communist China, India and the United States. These economies are discussed in terms of their actual goals, rather than in terms of the ideological justification they adopt. The authors explore the ways economies are organized, the various rates of economic growth and development, and the quality of each economy's performance. They also provide incisive analyses of such topics as individualism and collectivism, market economies, command economies, and those economies that are now either initiating development or have attained maturity. *April publication, 144 pages, probable price: \$1.50*

ECONOMICS AND THE MODERN WORLD

LAWRENCE ABBOTT, *Union College*

Here for the principles course is a text that takes a problem-centered approach to economic principles, interweaving facts and theory and presenting a clear treatment of the concepts, techniques and laws of economics as they relate to the modern world. "The strong points are its excellent treatment of interest theory; a realistic treatment of imperfect competition and the integration in presentation of micro-macro theory. . . . In my opinion, this book is the best principles book on the market today."—GEORGE R. GREEN, University of Pennsylvania. *Student Guide & Workbook and an Instructor's Manual are available. 880 pages, \$7.50*

Examination copies upon request.

Announcing
four
Graduate Fellowships
in
Business Administration
and
Agricultural Economics

Dear Professor and Administrator:

For the academic year 1962-1963 four full tuition plus \$100 per month stipend graduate fellowships are being offered by CONTINENTAL GRAIN COMPANY at each of the following four universities: Kansas State, Minnesota, Northwestern and Wharton at Pennsylvania. Two are in agricultural economics and two in business administration.

When you have occasion to advise your students about graduate training you may want to call their attention to these grants.

CONTINENTAL GRAIN COMPANY is happy to help make available the advantages of higher education to qualified young people who may not otherwise be able to pursue graduate study.

Bulletin board posters and wallet-size folders are available which provide details concerning these fellowships. Address Mr. Peter Mendelssohn, Vice President for Personnel Administration.

Most cordially,

Michael W. Burg
PRESIDENT

CONTINENTAL GRAIN COMPANY 2 Broadway, New York 4, N. Y.

TWO IMPORTANT TITLES

PREFACE TO ECONOMETRICS

by Michael J. Brennan, Jr., Brown University

This book provides an introduction to quantitative methods that can be understood by the undergraduate. The text material is as nontechnical as possible within limits of precision and accuracy, especially in the early chapters. Each new subject is introduced gradually to give the student time to digest the new learnings before taking up additional ones. Emphasis is placed on applications of economic theory, quantitative measurement, and tests of correctness of theory. An extensive group of problems is included at the end of each chapter.

BUSINESS CYCLES AND FORECASTING

2nd Edition—By Carl A. Dauten, Washington University

Attention to current trends in education for business is reflected in this revision. This new book provides an analytical presentation of cycle theory, forecasting problems, and policies for economic stability. Alternate business cycle theories are presented without critique. Keynesian theories are analyzed and then used in the description of the cyclical processes. Six new chapters are included in the second edition.

SOUTH-WESTERN PUBLISHING CO.

(Specialists in Business and Economic Education)

Cincinnati 27 New Rochelle, N.Y. Chicago 44 Burlingame, Calif. Dallas 2

The Real National Income of Soviet Russia Since 1928

By Abram Bergson. "A long, scholarly probe into raw data on Russian production and distribution shows that USSR's economic advances have been real indeed—although not quite as earthshaking as the Kremlin would have us believe."—*Saturday Review*.

"Professor Bergson's findings are the result of an exhaustive study of Soviet statistical methodology with exacting corrections for accuracy . . . a much needed addition to the factual findings on the Soviet Union . . . providing the student of Soviet affairs with valuable benchmarks."—*Christian Science Monitor*.

Attention is focused on the period of the plans to 1955. For these years the calculations provide the basis for a systematic reappraisal of the Soviet achievements. An attempt is also made to compare economic trends in the USSR with those in the USA. Finally, implications are considered for Russia's future progress.

A RAND Corporation Research Study

ECONOMICS IN ACTION, 2ND EDITION
Readings in Current Economic Issues

Shelley M. Mark, University of Hawaii and Daniel M. State, Michigan State University

The revised 1962 edition of this highly successful and provocative collection of readings on the crucial and controversial issues of economic policy places specific emphasis on the issues which will be important during the sixties. The divergent points of view show the process of deliberation that precedes policy formation and how these points of view may be reconciled in a private enterprise economy. Paperbound 504 pages \$3.95

ELEMENTARY MATHEMATICS OF PRICE THEORY

Clark Lee Allen, Southern Illinois University

This is a new and important book designed and class tested as a supplement to standard texts in price theory. It provides a clear and understandable terms the mathematics necessary for price theory for even the non-mathematical economist. Progressing from a simple treatment of graphs and functions to more complex problems in partial derivatives, maxima and minima and homogeneous functions, the book is at once a text and a workbook. Introduction to indifference curves, isoquants, and linear programming is presented in terms that make this book also ideal as a text for an introductory mathematical economics course. Paperbound 176 pages \$3.95

ECONOMIC DEVELOPMENT: The Underdeveloped World and the American Interest

Walter Krause, State University of Iowa

This stimulating, informative, and provocative book deals with the problems of economic development in the underdeveloped portions of the world, both from the standpoint of the underdeveloped countries themselves and from the American interest in this problem. ECONOMIC DEVELOPMENT is a guide to public policy that will well serve students, teachers, and others seriously interested in creative economic policy. Clothbound 538 pages \$8.50

A New Basic Text for Introductory Economics

ECONOMICS

Principles and Issues

By Delbert A. Snider, Professor of Economics, Miami University

A genuinely new approach to the study of economic principles is provided in this new basic text, but within the framework of the traditional content of a principles course. Each theoretical concept or principle is developed with the idea in mind of making it easy for the student to see its relevance to real-world problems and issues. The treatment is rigorous without being pedantic.

To accompany Snider's *Economics: Principles and Issues* a student *Workbook* prepared by Professor Wallace I. Edwards of Miami University will be available. It will contain material to assist the instructor in getting over important points to the student.

For Courses in Labor Economics

LABOR ECONOMICS

By Chester A. Morgan, State University of Iowa

In this new basic text for courses in labor economics or labor problems, the material is organized in a connected, continuous, and concise presentation. To assist in student understanding each chapter concludes with a summary which emphasizes the important points in the chapter.

A MESSAGE FROM McGRAW-HILL

One of the many changes in college and university education in recent years is the increasingly wide availability and use of non-required books, from quality paperbacks to large reference books. A key element in the development of book-centered campuses is the part played by college bookstores in stocking and displaying these books. When a college store carries such paperbacks as Heilbroner's *THE WORLDLY PHILOSOPHERS* or such reference sets as Schumpeter's *BUSINESS CYCLES*, it is exposing serious students to important works in their fields that go beyond the limits of their normal textbook reading. We urge you to support your local college store and we are urging all stores to carry adequate stocks of non-required books in all areas of economics and business administration. Some of our own titles are listed on these pages.

MAIN CURRENTS IN MODERN ECONOMICS

Economic Thought Since 1870

By Ben Seligman

A critical and penetrating review of the development, content, and relevance of contemporary economic thought. Mr. Seligman examines all the major figures and theories—from the socialist, marginalist, and historical economists of the nineteenth century to contemporary efforts in game theory, linear programming, input-output analysis, and welfare economics. A lively yet scholarly work, this is the only systematic survey of modern economic thought now available. **\$11.75**

BUSINESS AN INTRODUCTORY ANALYSIS

Here is a comprehensive view and analysis of American business viewed in the aggregate and in detail. The various subjects discussed are integrated through the concept of business as an interrelated system in which business firms use basic resources under the guidance of management and under the influence of social forces to accomplish objectives. Within the business system, the management and functions of the firm as the primary operating unit are described and analyzed, including a complete case history of a firm, 100 diagrams and original illustrations. March 15. 643 pp. + Index. \$7.50.

Eugene E. Jennings'

THE EXECUTIVE *Autocrat, Bureaucrat, Democrat*

Describing the crucial characteristics of the executive role today, this informative volume takes account of the fact that the most important view that the executive has is his view of what exactly constitutes the executive's role. The author describes three common executive views—autocratic, bureaucratic, and democratic—with many illustrations from business and government. The executive's problem is what ingredients from each to select in order to make an effective executive style. Coming in July.

NEW Economics Texts

from P-H

An Introduction to Econometrics

by **LAWRENCE R. KLEIN**, Wharton School, University of Pennsylvania

Here is a new book that brings econometrics within the reach of students and professional economists who have previously lacked the necessary background in mathematics. It is simultaneously suited to the beginning student who intends to make econometrics his specialty. The author gives the student a thorough appreciation of the subject by covering the main areas of applications in econometrics—demand analysis, production functions, cost functions, distribution of income, etc. He offers methods from an elementary viewpoint by critically examining these areas of application. And he bases much of his approach on the work of the great pioneers in econometrics—Schultz, Douglas, Dean, and others.

Klein uses a light mathematical approach—the only prerequisite being pre-college mathematics. He employs many examples from actual econometric studies using intuitive and illustrative reasoning. Problems are also included.

March, 1962

Approx. 288 pages

Text price: \$7.50

MATHEMATICS FOR ECONOMISTS: **An Elementary Survey**

by **TARO YAMANE**, New York University

Stressing clarity, this new text enables students to read mathematically oriented literature. It offers students in economics courses a wide variety of topics in mathematics, carefully selected to suit the particular needs of economists. Thoroughly covered are: set theory, calculus, differential and difference equations, vectors and matrices, probability, statistics, and game theory.

April, 1962

Approx. 544 pages

THE ECONOMIC GROWTH OF THE UNITED STATES (1790-1860)

by **DOUGLASS C. NORTH**, University of Washington

A new approach to the economic history of the U.S., this study has consolidated theory, statistics, and history. The study, in this manner, provides an analytical framework for examining economic growth with specific application to the U.S., and broader implications for the study of economic growth in general. The framework allows for the development of important new statistical data which are used to test hypotheses in this text. The major theme of the book is the influence of American foreign trade and shipping on the growth of the economy.

1961

304 pages

Capital in the American Economy: Its Formation and Financing

By Simon Kuznets

An examination of long-term trends in capital formation and financing in the United States, this study is organized primarily around the principal capital-using sectors of the economy. The analysis summarizes major trends in real capital formation and financing, and the factors that determined the trends. The significance of these factors for the future is studied. The book concludes and summarizes the findings of the National Bureau of Economic Research's study of capital formation and its financing, begun in 1950. *Published for the National Bureau of Economic Research.*

694 pages. \$12.00

The Share of Top Wealth-Holders in National Wealth

By Robert J. Lampman

This book offers estimates on how many living persons hold wealth above the minimum specified for filing of federal estate tax returns. These, along with estimates of aggregate national wealth, are used to develop a statement concerning changes in the concentration of wealth-holding between 1922 and 1956. Included also is an analysis of changes in the pattern of investment, or composition of investment of these top holders of wealth. *Published for the National Bureau of Economic Research.*

396 pages. Tables, charts. \$6.50

The Rate and Direction of Inventive Activity: Economic and Social Factors

The diversity of papers in this volume reflects the new and intensive interest in invention on the part of economists who have reawakened to the importance of invention in economic growth, industrial organization, defense economics, and management science. The topics covered range from description and analysis of the way our political economy allocates its inventive effort, to studies of the decision-making process in specific industrial laboratories. *Published for The National Bureau of Economic Research.*

**MANAGERIAL ECONOMICS: Text and Cases**

By ERWIN E. NEMMERS, *Northwestern University*. This book is a closely integrated presentation of the entire management process from the forecasting demand, production and cost, through pricing analysis and government regulation, and, finally, to the master planning of capital budgeting. 1962. Approx. 480 pages. Prob. \$10.25*

STATISTICAL CONTROLS in BUSINESS

By FREDERICK A. EKEBLAD, *Northwestern University*. Presents many innovations in the treatment of certain problems in statistical inference that are not available elsewhere. This treatment should arouse the critical interest of all professional statisticians. The statistical method is treated as a *unified whole* rather than as a collection of miscellaneous techniques and is oriented toward the problem of uncertainty. 1962. *In press*.

MATHEMATICAL FOUNDATIONS of ADMINISTRATION

By F. PARKER FOWLER, Jr., and E. W. SANDBERG, *both of Colorado State University*. The major theme of this book is that here is a mathematics text which covers the basic mathematical subjects prerequisite to understanding modern administration thought and practice and one that is written in a manner which seeks to motivate the non-mathematically oriented student. 1962. *In press*.

OPERATIONS RESEARCH in PRODUCTION and INVENTORY CONTROL

By FRED HANSSMANN, *International Business Machines Corporation*. Presents a comprehensive, up-to-date exposition of *all* the major technical developments that have occurred in O.R. during the past decade. 1962. 254 pages. Prob. \$8.95.*

CASEBOOK in PRODUCTION MANAGEMENT

By RAYMOND J. ZIEGLER, *University of Illinois*. 1962. Approx. 168 pages. Prob. \$3.95.

OXFORD BOOKS

ECONOMICS

By Abraham L. Gitlow,
Professor of Economics, New York University

The central theme unifying this new text is a major issue of our times: the contest between a free market system and economic authoritarianism. Economic growth, full employment, national security, and social welfare are among the principal contemporary problems considered as aspects of this basic theme. A sound, up-to-date text for introductory courses in economics, the volume combines careful analysis, thorough application of economic theory, and a dynamic writing style. Chapter summaries and bibliographies are included. An excellent teaching adjunct is available in the Gitlow and Diamond: *Economics Workbook*.

JUST PUBLISHED

LECTURES ON
**The Mathematical Method
in Analytical Economics**

by **JACOB T. SCHWARTZ**
Courant Institute of Mathematical Sciences, New York University

ECONOMICS is brought to the forefront of this presentation of the role of mathematics in economic analysis. Dr. Schwartz begins his discussion, as he began the series of lectures from which this book is taken, with the Leontief input-output model that forms the framework for all which follows. An introductory statement of price theory in the Leontief model is followed by a presentation of business cycle theory along the lines pioneered by Lloyd Metzler. The author then considers the contributions of Keynes, setting forth their dynamic foundations. Finally, the discussion is consolidated into a critique of the "general equilibrium" approach which Walras built as the ultimate form of the theory of supply and demand. To place the main results of theoretical analysis in proper perspective, the author makes rather frequent reference to statistical and empirical data. The text is in the lucid, colloquial style of the lecture room.

The reader of this book should know something of the basic theory of matrices and of linear transformations, and should have a working knowledge of elementary calculus. Wherever a more abstruse mathematical theorem comes into play, however, the author provides a careful statement and a reference to its proof.

Previews of new Spring titles . . .

THE SOVIET ECONOMY

Structure, Principles, Problems

By NICOLAS SPULBER, *Indiana University*

The first systematic analysis of the organization and functioning of the economy of the Soviet Union. Within the framework of modern economic theory, the author analyzes the basic strategy of Soviet economic development, the mechanism of Soviet planning, and the working principles behind any economy structured on the Soviet pattern.

INCOME, EMPLOYMENT AND ECONOMIC GROWTH

By WALLACE C. PETERSON,
University of Nebraska

In this unusually comprehensive aggregate theory text, extensive treatment is given to economic growth and the theory of public expenditures, and full chapters are also devoted to the impact of the foreign balance on the income level and the macroeconomic aspects of income distribution.

INTERMEDIATE PRICE AND INCOME THEORY

Revised Edition

By M. M. BOBER, *Lawrence College*

A thoroughgoing revision of a notable intermediate theory text, with broadened discussion of such subjects as the nature of economics, monopoly, the pricing of goods, and equilibrium.

. . . and a bit in its first season

PRINCIPLES OF A GROWING ECONOMY

By DANIEL HAMBERG, *University of Buffalo*

"Hamberg focuses on the major problems and shows the usefulness of analytical tools in shedding insights on the problems without cluttering up the exposition with peripheral institutional material . . . extensive use and mastery of the material in this volume would do much to raise the level of economic education."

NOW AVAILABLE

1961 SURVEY OF CONSUMER FINANCES

by G. Katona, C. Lininger, J. Morgan, and E. Mueller

Provides data on major consumer transactions in 1960, distribution of incomes in 1960, and of debts early in 1961, together with information on changes in consumer opinions, attitudes, and expectations in 1961.

XIV and 150 pages; 82 tables, 3 charts; \$4.00

In combination with the volume **1960 Survey of Consumer Finances** at a special pricing, the reader has available financial, demographic and attitudinal data from consumer surveys conducted by the Survey Research Center spanning sixteen years.

XXII and 310 pages, 124 tables, 13 charts

"This important volume brings together in compact and usable form a large number of significant facts concerning the financial affairs of U. S. households.

The research the results of which are presented here is of a high order. An attractive feature of the book is the tabular format which makes the tables unusually easy to consult and understand.—The detailed findings are of considerable theoretical and practical value to all students of consumer demand and to persons engaged in market research, as well as to policy makers in both business and government. The thoughtful consumer who is interested in budgeting and in evaluating his own financial status will find much in the way of guidance and assurance in the information herein presented."—FROM THE AMERICAN ECONOMIC REVIEW BOOK REVIEWS—DECEMBER 1961

BOTH VOLUMES FOR \$10.00

ECONOMICS of DEFENSE

The new Economics Division of the Operations Evaluation Group will appoint a limited number of imaginative economists holding advanced degrees to the staff during 1962.

They will explore new developments in applied military economics . . . often projects of their own selection . . . and within a favorable research environment. Also, individual publication in technical journals will be encouraged.

Representative problems of the division could include:

- *What is the most economical mix of weapons and delivery forces for stipulated capabilities?*
- *What criteria should determine whether the airlifting of spare parts is needed to support combat equipment?*
- *How can resources of given value contribute most to increasing fleet endurance?*

The Operations Evaluation Group . . . oldest (1942) continuing military operations research organization in this country . . . is civilian scientific advisor to the Chief of Naval Operations. OEG is a part of the Division of Sponsored Research of the Massachusetts Institute of Technology. **OEG**

OPERATIONS EVALUATION GROUP

employment by ability without discrimination.

MONEY, BANKING, AND MONETARY POLICY

Clifton H. Kreps, Jr., *University of North Carolina*

Ready in April! This book affords the student a thorough understanding of the national economic significance of monetary and banking policy. Theory is woven throughout in a highly integrated approach to the essential principles of money and banking. Attention is thus focused on the 'why' of institutional proc-

esses rather than the 'how.' The analytical discussion of the history of money and banking development places in true perspective the complex issues of theory and policy. Book contains ample question, problem, and bibliographical materials. 1962. 600 pp. \$7.50

ECONOMIC AND SOCIAL SECURITY—Second Edition **Public and Private Measures Against Economic Insecurity**

John G. Turnbull and C. Arthur Williams, Jr., *both University of Minnesota; and*
Earl F. Cheit, *University of California, Berkeley*

Just Published! Designed for students of social insurance and social security, this book offers a thorough discussion of the various public and private measures for extending economic security. Following the carefully planned and successful pattern established in the original volume, the Second Edition retains the use of ana-

lytical tools in evaluating the private and social insurances and assistances involved in such problems as old age and death, occupational disability and non-occupational illness, unemployment, and sub-standard working conditions. 2nd Ed., 1962. 500 pp. \$8.00

MARKETING—Seventh Edition

Theodore N. Beckman and William R. Davidson, *both The Ohio State University*

Just Published! This standard textbook provides a broad understanding and appreciation of the complete marketing process, its essential economic functions, and the institutions performing them. Giving proper emphasis to the managerial viewpoint, the Seventh Edition strengthens the social and economic coverage of marketing in all its significant implica-

tions. It includes discussions of physical distribution, the significance of consumer-oriented marketing management, quantitative methods of analysis, and marketing aspects of the behavioral sciences. Ample question and problem material. *Instructor's Manual* available. 7th Ed., 1962. 790 pp., illus. \$8.00

FUNDAMENTALS OF ECONOMICS

Ruby Turner Morris, *Connecticut College*

This highly readable textbook provides a broad background in economic theory and a detailed description of how the economic order operates. Student oriented throughout, it offers a unified, balanced treatment of micro- and macro-economics; treats supply and demand, monopoly, and pure competition. Practical application of theory is stressed. The analysis is dis-

tinguished for its clarity; important interrelationships, analytical comparisons, historical references, and contemporary applications are emphasized. Hundreds of charts and graphs illustrate and focus the discussion. *Student Workbook and Instructor's Manual* available. 1961. 878 pp. \$7.00

Important New College Textbooks

MODERN INTERNATIONAL ECONOMICS

by MAX J. WASSERMAN, Professor of Economics and Charles W. Hultman, Assistant Professor of Economics, both of the *University of Kentucky*

A fresh approach to international economics via balances of payments. An intensely practical college textbook. At the same time the theoretical parts of the book present a restatement of international trade theory tailored to requirements of a world composed of both open and partially closed economies. The book contains *several features not to be found in any other text* covering this subject.
